DISTRIBUTION OF EIGENVALUES
IN MULTIVARIATE STATISTICAL ANALYSIS

by

Steen A. Andersson†, Hans K. Brøns† and Søren Tolver Jensen†

ABSTRACT

Ten invariant multivariate testing problems involving the real, complex, or quaternion structure of covariance matrices are considered. In each problem the the maximal invariant statistic and its distribution are described, as well as the maximum likelihood estimators and likelihood ratio test statistics. These results are obtained by means of a new, unified method based on invariance arguments.

†The authors are Professors at the Institute of Mathematical Statistics of the University of Copenhagen. A portion of Andersson's work was done while visiting the Department of Statistics, University of Washington.
1. **INTRODUCTION.**

In this paper we consider ten testing problems in multivariate analysis. These are the problems of testing that (a) a covariance matrix has complex structure; (b) a covariance matrix with complex structure has real structure; (c) a covariance matrix with complex structure has quaternion structure; (d) a covariance matrix with quaternion structure has complex structure; (e) two sets of variates are independent, when their joint covariance matrix has real, complex, or quaternion structure; (f) two covariance matrices are identical, when both have real, complex, or quaternion structure. See Andersson [1] for a definition of these structures.

Some of these ten problems have been treated in the literature while the others are new. Together they occur in a fundamental way in a general algebraic theory of normal statistical models developed by Andersson, Brøns, and Jensen [5]. The class of normal models considered in [5] includes most of the structured families of covariance matrices which have appeared in the literature. It is shown in [5] that every testing problem where both the null hypothesis $H_0$ and the alternative hypothesis $H_1 (H_0 \neq H_1)$ belong to this class of models can be decomposed into simpler problems, each of which has the form of one of the ten problems described in (a) - (f) above.

In the present paper these ten testing problems are treated in detail in a unified manner suggested by the general theory. Each problem is invariant under a group of linear transformations, and our main aim is to obtain a concrete representation of the orbit projection, i.e., the maximal invariant statistic, and to find a representation of its distribution in terms of a density with
respect to the Lebesgue measure. Furthermore, the maximum likelihood estimators and likelihood ratio test statistics are obtained and their distributions discussed.

For each problem the representation of the orbit projection is obtained using results on simultaneous reduction of certain types of forms on vector spaces, i.e., simultaneous diagonalization of matrices. The orbit projection is thus represented in terms of eigenvalues of matrices with certain structures. Many of these results on simultaneous reduction of forms are well-known and all but one occur in Bourbaki [9]. The exception is apparently new and is given here as Lemma 8.

Traditionally, distributions in multivariate analysis are derived by calculations involving Jacobians of high dimensions. To use this method would require laborious calculations for each of the ten testing problems and, to make the proofs rigorous, it would be necessary to use arguments from differential geometry. In this paper a new method for obtaining the distribution of eigenvalues is presented in Lemmas 4, 5 and 6. This method, based on actions of a set of certain polynomial transformations on a space of positive definite symmetric matrices and on the space of eigenvalues, has several advantages over the classical approach. The method once presented for one problem, is readily adapted to all other problems. It is elementary, requiring only the calculation of $2 \times 2$ Jacobians at most. Lastly, the method is rigorous, not avoiding difficulties involving null sets of multiple eigenvalues.

In the existing literature about the complex normal and complex Wishart distribution one usually treats complex variates. It is important to note that in this paper all matrices considered have real elements; by "matrices with complex or quaternion structure" we refer to real matrices with certain additional structures defined by the corresponding complex and quaternion matrices.
The ten testing problems are treated in Sections 2-7. In each of these sections the joint density of the eigenvalues is derived up to an unspecified norming constant. The exact values of all norming constants are derived simultaneously in Section 8 using a new method involving recursion formulae. The moments of each likelihood ratio test statistic are readily obtained from these norming constants.

For the real case, the distribution of eigenvalues arising in problems (e) and (f) was obtained in 1939 by Hsu [14], Fisher [12], and Roy [19], and are treated in detail in Anderson [8]. For the complex case, the parallel results in (e) and (f) can be obtained from work of Khatri [15]. For the quaternion case these two results appear in the thesis of Gabrielsen [13] written under the supervision of S. Tolver Jensen, obtained by methods similar to Khatri's.

Problem (b) was first treated by Khatri [16], while problem (a) first appeared in Andersson [3], which also contains a statistical interpretation of the eigenvalues and eigenvectors. Further results on problems (a), (b), (c), and (d), including a study of the noncentral distributions, are given in Andersson and Perlman [6], [7].

Related problems concerning distributions of eigenvalues have been studied by mathematicians and physicists in the context of statistical mechanics; c.f. Mehta [17] and Porter [18].
2. TESTING THE HYPOTHESIS THAT A COVARIANCE MATRIX HAS COMPLEX STRUCTURE.

Let $E$ be a $p$-dimensional vector space over the field $\mathbb{C}$ of complex numbers. By restricting the scalar multiplication to the subfield $\mathbb{R}$ of real numbers $E$ is also a $2p$-dimensional vector space over $\mathbb{R}$, and if $e_1, \ldots, e_p$ is a basis for $E$ as a vector space over $\mathbb{C}$ then

\begin{equation}
(1) \quad e_1, \ldots, e_p, ie_1, \ldots, ie_p
\end{equation}

becomes a basis for $E$ as a vector space over $\mathbb{R}$. If $f$ is a $\mathbb{C}$-linear map of $E$ into $E$ with matrix $A+iB$ w.r.t. $e_1, \ldots, e_p$ then $f$ considered as a $\mathbb{R}$-linear map has matrix

\begin{equation}
(2) \quad \begin{pmatrix} A & -B \\ B & A \end{pmatrix}
\end{equation}

w.r.t. (1). Since composition of linear maps corresponds to multiplication of matrices it is seen that the set $GL(p, \mathbb{C})$ of nonsingular $2p \times 2p$ matrices of the form (2) for $q=2p$ is a subgroup of the group $GL(q, \mathbb{R})$ of all nonsingular $q \times q$ matrices.

Let $\phi: E \times E \to \mathbb{C}$ be a hermitian left sesquilinear or symmetric bilinear complex form on $E$ (see [9] or [1]) and $C+iD=(\phi(e_a, e_b))$ the matrix of $\phi$ w.r.t. $e_1, \ldots, e_p$. Then $\delta=\text{Re} \circ \phi: E \times E \to \mathbb{R}$, where $\text{Re}$ denotes the real part of a complex number, is a symmetric bilinear real form on $E$.

The form $\phi$ is hermitian left sesquilinear if and only if $C+iD$ is hermitian, i.e., $C$ is symmetric and $D$ is antisymmetric. In this case the matrix of $\delta$ w.r.t. (1) is
Moreover, \( \phi \circ (f \times f) \) is also hermitian left sesquilinear and the matrix of \( \text{Re} \circ (\phi \circ (f \times f)) = (\text{Re} \circ \phi) \circ (f \times f) \) w.r.t. (1) is

\[
\begin{pmatrix}
C & -D \\
D & C
\end{pmatrix}.
\]

Since \( \phi \) is positive definite if and only if \( \text{Re} \circ \phi \) is positive definite it follows that the action

\[
\text{GL}(p, \mathbb{C}) \times H^+(p, \mathbb{C}) \to H^+(p, \mathbb{C})
\]

\[
(M, T) \mapsto MTM',
\]

where \( H^+(p, \mathbb{C}) \) is the set of positive definite matrices of the form (3), is well defined. It follows from the first equation in (14) below that this action is transitive. Furthermore, for \( q = 2p \) the action (5) is a restriction of the transitive action

\[
\text{GL}(q, \mathbb{R}) \times H^+(q, \mathbb{R}) \to H^+(q, \mathbb{R})
\]

\[
(M, S) \mapsto MSM',
\]

where \( H^+(q, \mathbb{R}) \) is the set of all positive definite symmetric \( q \times q \) matrices. Since the action (6) is proper ([10], p. III.27) it follows that the action (5) is also proper.
The form $\phi$ is symmetric bilinear if and only if $C + iD$ is symmetric, i.e., $C$ and $D$ are symmetric. In this case the matrix of $\phi$ w.r.t. the basis (1) is

\[
\begin{pmatrix}
  C & -D \\
  -D & -C
\end{pmatrix}
\]

Moreover, $\phi \circ (f \times f)$ is also symmetric bilinear and the matrix of $\text{Re} \circ (\phi \circ (f \times f)) = (\text{Re} \circ \phi) \circ (f \times f)$ w.r.t. (1) is

\[
\begin{pmatrix}
  A & -B \\
  B & A
\end{pmatrix}'
\begin{pmatrix}
  C & -D \\
  -D & -C
\end{pmatrix}
\begin{pmatrix}
  A & -B \\
  B & A
\end{pmatrix} \in S(p, C)
\]

where $S(p, C)$ is the set of matrices of the form (7).

We are now ready to consider the first statistical problem. Let $x_1, \ldots, x_N$, $N \geq 2p$, be independently distributed observations from a normal distribution on $\mathbb{R}^{2p}$ with mean vector 0 and unknown covariance matrix $\Sigma \in H^+(2p, \mathbb{R})$. A minimal sufficient statistic is the empirical covariance matrix $S = \frac{1}{N} \sum x_n x_n'$, the maximum likelihood estimator, which follows a Wishart distribution on $H^+(2p, \mathbb{R})$ with $N$ degrees of freedom and parameter $\frac{1}{N} \Sigma$. This distribution has the density

\[
\left( \frac{\det S}{\det \Sigma} \right)^{N/2} \exp(-N/2(\text{tr}^{-1}_\Sigma S)), S \in H^+(2p, \mathbb{R})
\]

w.r.t. a measure $\nu = \nu_{\mathbb{R}, 2p, N}$ on $H^+(2p, \mathbb{R})$, which is invariant under the action (6). Since this action is transitive $\nu$ is uniquely determined by the condition that the integral of (9) is 1.
Let $H_0$ denote the hypothesis that $\Sigma \in H^+(p, \mathbb{C})$, i.e., that $\Sigma$ has complex structure. The statistical problem of testing $H_0$ is invariant under the restriction of the action (6) to the subgroup $GL(p, \mathbb{C})$. Every invariant test statistic has a unique factorization through the orbit projection

\[ \Pi: H^+(2p, \mathbb{R}) \to H^+(2p, \mathbb{R})/GL(p, \mathbb{C}), \]

where the right hand side denotes the set of orbits. The main problem is to find a representation of (10) as a function into $\mathbb{R}^\ell$ for some $\ell$ and, when $H_0$ is true, to represent the distribution of $\Pi$ by a density w.r.t. a Lebesgue measure on $\mathbb{R}^\ell$.

Let

\[ J = J_p = \begin{pmatrix} 0 & -I_p \\ I_p & 0 \end{pmatrix}, \]

where $I_p$ is the $p \times p$ identity matrix. It is seen that the linear map

\[ t: H^+(2p, \mathbb{R}) \to H^+(p, \mathbb{C}) \]

\[ S = \begin{pmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{pmatrix} \to 1/2 \begin{pmatrix} S_{11} + S_{22} & S_{12} - S_{21} \\ S_{21} - S_{12} & S_{11} + S_{22} \end{pmatrix} \]

is well defined, because $t(S) = \frac{1}{2}(S + JSJ') \in H^+(p, \mathbb{C})$. Since $J$ is the matrix (w.r.t. the basis (1)) for scalar multiplication by $i$, it follows that $J$ commutes with all matrices of the form (2), and thus also
that \( t \) commutes with the actions of \( \text{GL}(p, \mathbb{C}) \). Moreover, the residual

\[
S - t(S) = \frac{1}{2} \begin{pmatrix}
S_{11} - S_{22} & S_{12} + S_{21} \\
S_{21} + S_{12} & S_{22} - S_{11}
\end{pmatrix}
\]

has the form (7).

**Lemma 1.** Let \( \phi \) be a positive definite hermitian left sesquilinear form and \( \psi \) a symmetric bilinear form on \( E \). Then there exists a basis for \( E \) such that the matrices of \( \phi \) and \( \psi \) are respectively the identity matrix \( I_p \) and a diagonal matrix

\[
\Lambda = \begin{pmatrix}
\lambda_1 & 0 \\
0 & \ddots \\
0 & 0 & \lambda_p
\end{pmatrix} = \text{diag}(\lambda_1, \ldots, \lambda_p),
\]

where \( \lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_p \geq 0 \).

**Proof.** Bourbaki [9], p. 123.

An equivalent formulation of the lemma is that there exists a \( \mathbb{C} \)-linear map \( f:E \to E \) such that \( \phi(f \times f) \) and \( \psi(f \times f) \) have matrices \( I_p \) and \( \Lambda \) resp. w.r.t. the original basis \( e_1, \ldots, e_p \). Since the matrices for \( \text{Re} \circ \phi \) and \( \text{Re} \circ \psi \) transform according to (4) and (8) the lemma also has an equivalent formulation in terms of \( 2p \times 2p \) real matrices. Let \( T \in H^+(p, \mathbb{C}) \) and \( \text{Re} \in \mathcal{S}(p, \mathbb{C}) \). Then there exists an \( M \in \text{GL}(p, \mathbb{C}) \) such that

\[
MTM' = I_{2p} \quad \text{and} \quad MRM' = \begin{pmatrix}
\Lambda & 0 \\
0 & -\Lambda
\end{pmatrix}.
\]
It is seen from (14) that $\pm \lambda_1, \ldots, \pm \lambda_p$ are uniquely determined as the eigenvalues of $R$ w.r.t. $T$, i.e., the solutions to the equation

\[(15) \quad \det(R - \lambda T) = 0.\]

From (14) and (15) with $T = t(S)$ and $R = S - t(S)$ and the fact that $S = t(S) + (S - t(S))$ is positive definite, it then follows that there exists an $M \in GL(p, \mathbb{C})$ such that

\[(16) \quad MSM' = \begin{bmatrix} I_p + \Lambda & 0 \\ 0 & I_p - \Lambda \end{bmatrix} \]

and that (10) can be represented by

\[(17) \quad \pi: H^+(2p, \mathbb{R}) \to \Lambda_p,\]

where $\Lambda_p = \{(\lambda_1, \ldots, \lambda_p) \in \mathbb{R}^p | 1 > \lambda_1 \geq \ldots \geq \lambda_p \geq 0\}$ and $\pi(S)$ is the ordered family of nonnegative eigenvalues of $S - t(S)$ w.r.t. $t(S)$.

That the function $\pi$ in (17) is continuous follows from Lemma 2. The ordered family of eigenvalues of a symmetric $m \times m$ real matrix $R$ w.r.t. a positive definite symmetric $m \times m$ real matrix $T$ depends continuously on $(T, R)$.

**Proof.** Let $(T_n, R_n)$ be a sequence of pairs of a positive definite symmetric $m \times m$ real matrix and a symmetric $m \times m$ real matrix such that $(T_n, R_n) \to (T, R)$. One has to show that the ordered family $(\lambda_{1n}, \ldots, \lambda_{mn})$ of solutions to the equation

$$\det(R_n - \lambda T_n) = \prod_{i=1}^m (\lambda - \lambda_{1n}) = 0$$

converges to the ordered family $(\lambda_1, \ldots, \lambda_m)$ of solutions to the equation

$$\det(R - \lambda T) = \prod_{i=1}^m (\lambda - \lambda_i) = 0.$$
Since the sequence \((T_n, R_n)\) is bounded, the sequence \((\lambda_{1n}, \ldots, \lambda_{mn})\) is also bounded. It is therefore enough to show that every convergent subsequence \((\lambda_{1n}, \ldots, \lambda_{mn})\) converges to \((\lambda_1, \ldots, \lambda_m)\). But if \((\lambda_{1n}, \ldots, \lambda_{mn}) \to (\mu_1, \ldots, \mu_m)\) it follows that \(a_n \Pi(\lambda - \lambda_{1n})\) converges to both \(a \Pi(\lambda - \lambda_i)\) and \(a \Pi(\lambda - \mu_i)\), and the uniqueness of the roots of a polynomial gives that \((\mu_1, \ldots, \mu_m) = (\lambda_1, \ldots, \lambda_m)\).

**Remark.** Since the action of \(\text{GL}(p, \mathbb{C})\) on \(H^+(2p, \mathbb{R})\) is proper it is known that the final topology induced by \(\Pi\) on \(H^+(2p, \mathbb{R})/\text{GL}(p, \mathbb{C})\) is locally compact ([11], p. 39). Since the right hand side of (16) depends continuously on \((\lambda_1, \ldots, \lambda_p) \in \Lambda_p\), the lemma above shows in fact that the representation of (10) by (17) is also topological, i.e., the identification of \(H^+(2p, \mathbb{R})/\text{GL}(p, \mathbb{C})\) with \(\Lambda_p\) is a homeomorphism.

**Theorem 1.** The maximum likelihood estimator of \(\Sigma\) under \(H_0\) is \(t(S)\) and the likelihood ratio statistic for testing \(H_0\) is

\[
(18) \quad \prod_{\gamma=1}^{p} (1 - \lambda_{\gamma}^2)^{N/2},
\]

where \((\lambda_1, \ldots, \lambda_p) = \Pi(S)\). Under the hypothesis \(H_0\) the statistics \(t(S)\) and \(\Pi(S)\) are independently distributed. The distribution of \(t(S)\) has density

\[
(19) \quad \frac{\det T}{\det \Sigma}^{N/2} \exp \left( - \frac{N}{2}(\text{tr} \Sigma^{-1} T) \right), T \in H^+(p, \mathbb{C})
\]

w.r.t. a unique measure \(\nu_{C,p,N}\) which is invariant under the action (5).

The distribution of \(\Pi(S)\) has density (18) w.r.t. a measure \(\kappa\) on \(\Lambda_p\) which is uniquely defined by
Furthermore, $\kappa$ has the density

$$
\pi (\lambda_\alpha^2 - \lambda_\beta^2) \prod_{1 \leq \alpha < \beta \leq p} \lambda_\gamma (1 - \lambda_\gamma^2)^{-2p+1/2} \quad 1 \leq \alpha < \beta \leq p, \quad \gamma = 1
$$

w.r.t. a Lebesgue measure on $\Lambda_p$.

Remark. The distribution given by the density (19) is the complex Wishart distribution with $N$ degrees of freedom and parameter

$$
\frac{1}{N} \sum_{\Sigma \in H^+(p, \mathbb{C})} \exp (-N/2 \text{tr}(\Sigma^{-1} T)),
$$

where $T = t(S)$ and $(\lambda_1, \ldots, \lambda_p) = \Pi(S)$. The first sentence of the theorem follows from (22).

Next, the distribution of $(t, \Pi)(S) \equiv (t(S), \Pi(S))$ has the density (22), where $T \in H^+(p, \mathbb{C})$ and $(\lambda_1, \ldots, \lambda_p) \in \Lambda_p$, w.r.t. $(t, \Pi)(\nu_{\mathbb{R}, 2p, N})$. Since the action (5) is transitive, $\nu_{\mathbb{C}, p, N}$ is uniquely determined by the condition that the integral of (19) must be 1. The theorem now follows from Lemmas 3 and 5 below.
Lemma 3. Let $G$ be a locally compact group, which acts properly on a locally compact space $X$ and properly and transitively on a locally compact space $Y$. Let furthermore $t: X \to Y$ be a continuous map which commutes with the actions of $G$, and let $\pi: X \to X/G$ denote the orbit projection. Then the map $(t, \pi)$ is proper. If $\nu$ is an invariant measure on $X$ and $\nu_0$ is an invariant measure on $Y$ then there exists a unique measure $\kappa$ on the locally compact space $X/G$ such that $(t, \pi)(\nu) = \nu_0 \otimes \kappa$.

Proof. (Compare Bourbaki [11], p. 39) Since the action of $G$ on $X$ is proper the final topology on $X/G$ is locally compact and every compact subset of $X/G$ has the form $\pi(K)$, where $K \subseteq X$ is compact. Thus every compact subset of $Y \times X/G$ is contained in a compact subset of the form $L \times \pi(K)$, where $L \subseteq Y$ is compact. One has to show that $(t, \pi)^{-1}(L \times \pi(K)) \subseteq X$ is compact. Since the action of $G$ on $Y$ is proper, the set 

$\{g \in G \mid \exists z \in K: gt(z) \in L\} = \{g \in G \mid gt(K) \cap L \neq \emptyset\} \equiv P(t(K), L)$ is compact, (Bourbaki [10], p. III.33). Thus one has $(t, \pi)^{-1}(L \times \pi(K)) = \{x \in X \mid t(x) \in L, \pi(x) \in \pi(K)\} = \{x \in X \mid t(x) \in L, \exists z \in K \exists g \in G: x = gz\} = \{gz \in X \mid z \in K, g \in G: gt(z) \in L\} \subseteq P(t(K), L)K$, which is compact.

To prove the second assertion, let $h$ and $f$ be non-negative continuous functions with compact supports on $Y$ and $X/G$ respectively. Since $t$ commutes with the actions it is seen that the positive linear map $h \to \int h(t(x)) f(\pi(x)) \, dv(x)$ defines an invariant measure on $Y$. Because of the uniqueness of an invariant measure on $Y$ there exists a non-negative constant $\kappa(f)$ such that $\nu_0(h) \kappa(f) = \int h(t(x)) f(\pi(x)) \, dv(x)$. It is easy to see that $\kappa$ is a positive linear map, so that $\kappa$ is a measure on $X/G$. \qed
All assertions in Theorem 1 have now been proved except for (21). To prove this we have developed a new method, based on invariance under polynomial transformations, which also can be applied to the eigenvalue problems in the following sections.

Since \( H^+(p, \mathbb{C}) \cap S(p, \mathbb{C}) = \emptyset \) and \( t(T) = T \) for \( T \in H^+(p, \mathbb{C}) \), it follows that the linear map

\[
(23) \quad H^+(2p, \mathbb{R}) \to E
\]

\[
S \to (t(S), S - t(S)),
\]

where \( E = \{(T, R) \in H^+(p, \mathbb{C}) \times \mathbb{S}(p, \mathbb{C}) | T + R \in H^+(2p, \mathbb{R})\} \), is well-defined, one-to-one, and onto. The fact that \( t \) commutes with the actions of \( GL(p, \mathbb{C}) \) gives that (23) also commutes with the actions of \( GL(p, \mathbb{C}) \) on \( H^+(2p, \mathbb{R}) \) and \( E \), the latter given by

\[
(24) \quad GL(p, \mathbb{C}) \times E \to E
\]

\[
(M, (T, R)) \to (MTM', MRM'),
\]

which is well-defined because of (8). Let \( r(x) = \sum_{j=0}^{m} a_j x^{2j+1} \) be an odd real polynomial such that \( r(0) = 0, r(1) = 1, \) and \( Dr(x) > 0, \ 0 < x < 1. \) Let

\[
(25) \quad r(T, R) = \sum_{j=0}^{m} a_j (RT^{-1})^{2j} R, (T, R) \in E,
\]

and

\[
(26) \quad \hat{r}(S) = t(S) + r(t(S), S - t(S)), S \in H^+(2p, \mathbb{R}).
\]

Lemma 4. The map \( \hat{r} \) defined by (26) is a diffeomorphism of \( H^+(2p, \mathbb{R}) \) onto \( H^+(2p, \mathbb{R}) \) which commutes with the action of \( GL(p, \mathbb{C}) \). Moreover,
where \( r \) is the homeomorphism of \( \Lambda_p \) onto \( \Lambda_p \) given by
\[
(28) \quad r(\lambda_1, \ldots, \lambda_p) = (r(\lambda_1), \ldots, r(\lambda_p)), \quad (\lambda_1, \ldots, \lambda_p) \in \Lambda_p.
\]

The Jacobian of \( r \) is an invariant function and is given by
\[
(29) \quad \det D \tilde{r}(S) = Dr(0)^2 |C| \prod_{A} \frac{r(\lambda_\alpha)^2 - r(\lambda_\beta)^2}{\lambda_\alpha^2 - \lambda_\beta^2} \prod_{B} \frac{r(\lambda_\alpha)}{\lambda_\alpha} Dr(\lambda_\alpha),
\]
where \((\lambda_1, \ldots, \lambda_p) = \Pi(S), \quad A \equiv A(\lambda_1, \ldots, \lambda_p) = \{(\alpha, \beta) | \alpha < \beta, \lambda_\alpha > \lambda_\beta \}, \quad B \equiv B(\lambda_1, \ldots, \lambda_p) = \{(\alpha, \beta) | \alpha < \beta, \lambda_\alpha = \lambda_\beta > 0 \}, \quad C \equiv C(\lambda_1, \ldots, \lambda_p) = \{(\alpha, \beta) | \alpha \leq \beta, \lambda_\alpha = \lambda_\beta = 0 \}, \quad \text{and } |C| \text{ denotes the number of elements in } C.

**Proof.** It is seen from (25) that \( r(MM', MRM') = Mr(T, R)M' \) for \( M \in GL(p, \mathbb{C}) \) and \( (T, R) \in E \). It follows from the representation (14) that \( M \) can be chosen such that \( MM' = I_{2p} \) and \( MM' = R_o = \text{diag}(\lambda_1, \ldots, \lambda_p, -\lambda_1, \ldots, -\lambda_p) \). Then \( Mr(T, R)M' = r(MM', MRM') = r(I_{2p}, R_o) = \text{diag}(r(\lambda_1), \ldots, r(\lambda_p), -r(\lambda_1), \ldots, -r(\lambda_p)) \), and it is seen that \( (T, r(T, R)) \in E \). Using the isomorphism (23) it is then seen that \( \tilde{r}(S) \in H^+(2p, \mathbb{R}) \), \( \tilde{r} \) corresponds to the mapping \( (T, R) \rightarrow (T, r(T, R)) \) of \( E \) into \( E \), \( \tilde{r} \) commutes with the action, and that (27) holds.

The next step is to show that \( \tilde{r} \) is one-to-one. Since \( \tilde{r} \) commutes with the action of \( GL(p, \mathbb{C}) \) it is enough to show that \( (T, r(T, R)) = (I_{2p}, r(I_{2p}, R_o)) \) implies that \( T = I_{2p} \) and \( R = R_o \). This means one has to show that \( r(I_{2p}, R) = r(I_{2p}, R_o) \) implies that \( R = R_o \). Since \( \tilde{r} \) is
one-to-one it follows that $R$ and $R_0$ have the same eigenvalues w.r.t. $I_{2p}$ or in other words there exists $M \in \text{GL}(p, \mathbb{C})$ such that $MM' = I_{2p}$ and $MR_0 M' = R$. Then $Mr(I_{2p}, R_0) M' = r(MM', MR_0 M') = r(I_{2p}, R) = r(I_{2p}, R_0) = \text{diag}(r(\lambda_1), \ldots, r(\lambda_p), -r(\lambda_1), \ldots, -r(\lambda_p))$, and since $M$ is orthogonal, one has

\[(30) \quad M r(I_{2p}, R_0) = r(I_{2p}, R_0) M.\]

For every odd polynomial $q$, (30) implies that $M$ commutes with $\text{diag}(q(r(\lambda_1)), \ldots, q(r(\lambda_p)), -q(r(\lambda_1)), \ldots, -q(r(\lambda_p)))$. Since $q$ can be chosen such that $q(r(\lambda_\alpha)) = \lambda_\alpha$, $\alpha = 1, \ldots, p$, one obtains that $M$ commutes with $R_0$ and therefore that $R = MR_0 M' = R_0 MM' = R_0$. Therefore $\hat{\gamma}$ is one-to-one.

Since $\hat{\gamma}$ commutes with the action of $\text{GL}(p, \mathbb{C})$ and $\overline{r}$ is onto it follows from (27) that $\hat{\gamma}$ also is onto.

The fact that $\hat{\gamma}$ commutes with the action gives that the Jacobian is an invariant function. It is therefore enough to calculate $\det D\hat{\gamma}(S)$ when $S = I_{2p} + R_0$. Using the isomorphism (23) the Jacobian of $\hat{\gamma}$ is the same as the Jacobian of the mapping $(T, R) \mapsto (T, r(T, R))$, which again is the same as the Jacobian of $R \mapsto r(T, R)$. Thus one has to find the absolute value of the determinant of the mapping

\[(31) \quad dR \mapsto \sum_{j=0}^{m} \sum_{k=0}^{2j-k} a_j^k R_0^k(dR) R_0.\]

Since $dR$ has the form (7), where $C = (c_{\alpha \beta})$ and $D = (d_{\alpha \beta})$, it is seen that the mapping (31) multiplies $c_{\alpha \beta}$, $\alpha \leq \beta$, by
The Jacobian is therefore a product of all these factors. If \((\alpha, \beta) \in B\) (32) is equal to \(\text{Dr}(\lambda_\alpha)\) and (33) is equal to \(r(\lambda_\alpha)/\lambda_\alpha\). If \((\alpha, \beta) \in C\) both (32) and (33) are equal to \(\text{Dr}(0)\). If \((\alpha, \beta) \in A\) we have two geometric progressions, and it is seen that (32) is equal to 

\[
\frac{(r(\lambda_\alpha) - r(\lambda_\beta))/(\lambda_\alpha - \lambda_\beta)}{r(\lambda_\alpha + r(\lambda_\beta))/(\lambda_\alpha + \lambda_\beta)}.
\]

Since (29) is positive it follows that \(\varphi^{-1}\) is differentiable.

**Lemma 5.** The measure \(\kappa\) in Theorem 1 has the density (21) w.r.t. a Lebesgue measure on \(\Lambda_p\).

**Proof.** The invariant measure \(\nu_{A,2p,N}\) on \(H^+(2p, \mathbb{R})\) has density

\[|\text{det} S|^{(2p+1)/2}\] w.r.t. a Lebesgue measure ([11], p. 93). Since \(\varphi\) is a diffeomorphism \(\varphi^{-1}(\nu_{A,2p,N})\) has the density

\[
(\text{det } S/\text{det } \varphi(S))^{(2p+1)/2}|\text{det } \varphi(S)|
\]

w.r.t. \(\nu_{A,2p,N}\). It follows from Lemma 4 and (16) that (34) is an invariant function \(g(\Phi(S)), S \in H^+(2p, \mathbb{R})\), where
Using (27) we obtain that 

$$
\psi_{\mathcal{C},p,N} \otimes r^{-1}(\kappa) = (1 \times r^{-1})(\psi_{\mathcal{C},p,N} \otimes \kappa) = (1 \times r^{-1})(t,\Pi)(\psi_{\mathcal{R},2p,N}) = (t,\Pi)((g \circ \Pi)\psi_{\mathcal{R},2p,N}) = \psi_{\mathcal{C},p,N} \otimes g\kappa,
$$

so it is seen that

$$
(36) \quad \bar{r}^{-1}(\kappa) = g\kappa.
$$

Let

$$
k(\lambda_1, \ldots, \lambda_p) = \prod_{\gamma=1}^{p} (1 - \lambda_\gamma^2)^{-2(2p+1)/2} \prod_{A}^{(\lambda_\alpha^2 - \lambda_\beta^2)} \prod_{B}^{\lambda_\alpha} (\lambda_1, \ldots, \lambda_p) \in \Lambda_p
$$

and let \( \mu = (1/k)\kappa \). Then \( \kappa \) has density \( k(>0) \) w.r.t. \( \mu \) and it follows from (35) that \( \bar{r}^{-1}(\mu) \) has density

$$
Dr(0)^2|C| \prod_{B} Dr(\lambda_\alpha)
$$

w.r.t. \( \mu \). By considering the restrictions of \( \mu \) to the "faces"

$$
\{(\lambda_1, \ldots, \lambda_p) \in \mathbb{R}^p \mid 1 > \lambda_1 > \ldots > \lambda_{m_1} > \lambda_{m_1+1} = \ldots = \lambda_{m_q} > \lambda_{m_q+1} = \ldots = \lambda_p = 0\}
$$

of \( \Lambda_p \), where \( 1 \leq m_1 < \ldots < m_q \leq p \), \( q = 1,2,\ldots,p \), it follows from the
next lemma that \( \mu \) is a Lebesgue measure on \( \Lambda_p \). Hence \( \mu \) is concentrated on the interior of \( \Lambda_p \), and on this subset \( k(\lambda_1, \ldots, \lambda_p) \) is equal to (21).

**Lemma 6.** Let \( \mu \) be a measure on the interior \( \{ (\delta_1, \ldots, \delta_q) \in \mathbb{R}^q \mid 1 > \delta_1 > \cdots > \delta_q > 0 \} \) of \( \Lambda_q \), \( q = 1, 2, \ldots \), such that \( \overline{r}^{-1}(\mu) \) has density

\[
\prod_{\alpha=1}^{q} Dr(\delta_{\alpha})^{n_{\alpha}},
\]

\( n_{\alpha} = 1, 2, \ldots, \alpha = 1, \ldots, q, \) w.r.t. \( \mu \) for any uneven polynomial \( r \) such that \( r(0) = 0, r(1) = 1, \) and \( Dr(x) > 0, 0 < x < 1. \) If \( \mu \) is not identically zero then \( n_{\alpha} = 1, \alpha = 1, \ldots, q, \) and \( \mu \) is the restriction of a Lebesgue measure to the interior of \( \Lambda_q \).

**Proof.** The condition on \( \mu \) is that

\[
\int fd\mu = \int f(r(\delta_1), \ldots, r(\delta_q)) \prod_{\alpha=1}^{q} Dr(\delta_{\alpha})^{n_{\alpha}} d\mu(\delta_1, \ldots, \delta_q)
\]

for any continuous function \( f \) with compact support. For a fixed \( f \) it follows from the Weierstrass approximation theorem that (37) even holds for any continuously differentiable function \( r \) with \( r(0) = 0, r(1) = 1, \) and \( Dr(x) > 0, 0 < x < 1. \) [If the polynomials \( q_n \) tend uniformly to \( \sqrt{Dr} \) on \( [0,1] \) then the polynomials \( r_n(x) = \int_0^x q_n(t)^2 dt + x(1 - \int_0^1 q_n(t)^2 dt) \) are odd, \( r_n(0) = 0, r_n(1) = 1, \) and \( r_n \) and \( Dr_n \) tend uniformly to \( r \) and \( Dr, \) respectively, on \( [0,1] \). Hence \( Dr_n(x) > 0, 0 < x < 1, \) for \( n \) sufficiently large.] By monotone convergence (37) is extended
to the case where \( f \) is an indicator function for a compact subset.

Let \( I = X[a_\alpha, a_\alpha + c_\alpha] \) and \( J = X[b_\alpha, b_\alpha + c_\alpha] \) be two rectangles in the interior of \( \mathbb{R}^q \) with sidelengths \( c_\alpha > 0, \alpha = 1, \ldots, q \). Since \( 1 > a_1 + c_1 > a_1 > \cdots > a_p + c_p > a_p > 0 \) and \( 1 > b_1 + c_1 > b_1 > \cdots > b_p + c_p > b_p > 0 \) there exists a continuously differentiable function \( r \) with \( r(0) = 0, r(1) = 1 \), and \( Dr(x) > 0, 0 < x < 1 \), such that \( r(x) = x + (b_\alpha - a_\alpha) \), \( x \in [a_\alpha, a_\alpha + c_\alpha], \alpha = 1, \ldots, q \). Then \( Dr(x) = 1 \) for \( x \in [a_\alpha, a_\alpha + c_\alpha], \alpha = 1, \ldots, q \), and if \( f \) is the indicator function of \( J \) it follows from (37) that \( \mu(I) = \mu(J) \). Hence \( \mu \) is translation invariant. If \( \mu \) is not identically zero it must be the restriction of a Lebesgue measure, and then it is clear that \( n_\alpha = 1, \alpha = 1, \ldots, q \).

3. TESTING THE HYPOTHESIS THAT A COVARIANCE MATRIX WITH COMPLEX STRUCTURE HAS REAL STRUCTURE.

Let \( x_1, \ldots, x_N, N \geq p \), be i.i.d. observations from a normal distribution on \( \mathbb{R}^{2p} \) with mean vector \( 0 \) and unknown covariance matrix

\[
\Sigma = \begin{pmatrix} \Gamma & -\Psi \\ \Psi & \Gamma \end{pmatrix} \in \mathbb{C}^{p \times p}
\]

It follows from section 2 that the empirical covariance matrix transformed by the mapping (12) is a minimal sufficient reduction which follows a complex Wishart distribution with \( N \) degrees of freedom and parameter \( \frac{1}{N} \Sigma \). This distribution has the density (19) w.r.t. \( \psi^c, p, N \).
For $p > 1$ we shall consider the hypothesis $H_0$ that $\psi = 0$, i.e., that $\Sigma$ has a real structure. The statistical problem of testing $H_0$ is invariant under the restriction of the action (5) to the subgroup $\text{GL}(p, \mathbb{R}) \otimes I_2 = \{ \text{diag}(A, A) | A \in \text{GL}(p, \mathbb{R}) \}$ of $\text{GL}(p, \mathbb{C})$. The problem is to find a representation of the orbit projection

$$\Pi: H^+(p, \mathbb{C}) \to H^+(p, \mathbb{C})/\text{GL}(p, \mathbb{R}) \otimes I_2$$

and, when $H_0$ is true, the distribution of $\Pi$.

The group $\text{GL}(p, \mathbb{R}) \otimes I_2$ acts on $H^+(p, \mathbb{R}) \otimes I_2 = \{ \text{diag}(H, H) | H \in H^+(p, \mathbb{R}) \}$ by restriction of (5). The linear map

$$t: H^+(p, \mathbb{C}) \to H^+(p, \mathbb{R}) \otimes I_2$$

$$S = \begin{bmatrix} H & -F \\ F & H \end{bmatrix} \to \begin{bmatrix} H & 0 \\ 0 & H \end{bmatrix}$$

commutes with the actions of $\text{GL}(p, \mathbb{R}) \otimes I_2$, and the residual

$$S - t(S) = \begin{bmatrix} 0 & -F \\ F & 0 \end{bmatrix} \in A(p, \mathbb{R}) \otimes J_1,$$

where

$$A(p, \mathbb{R}) \otimes J_1 = \left\{ \begin{bmatrix} 0 & -F \\ F & 0 \end{bmatrix} | F \in A(p, \mathbb{R}) \right\}$$

and $A(p, \mathbb{R})$ is the set of all antisymmetric $p \times p$ real matrices.
Lemma 7. Let $\phi$ be a positive definite symmetric bilinear real form and $\psi$ an antisymmetric bilinear real form on a $p$-dimensional real vector space. Then there exists a basis such that the matrices of $\phi$ and $\psi$ are $I_p$ and

$\Lambda = \begin{pmatrix}
0 & -\lambda_1 & 0 & 0 & \cdots & 0 \\
+\lambda_1 & 0 & 0 & 0 & \cdots & 0 \\
0 & 0 & 0 & -\lambda_2 & \cdots & 0 \\
0 & 0 & \lambda_2 & 0 & \cdots & 0 \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
\end{pmatrix}$

(39)

respectively, where $\lambda_1 \geq \cdots \geq \lambda_{\lfloor p/2 \rfloor} \geq 0$.

Proof. Bourbaki [9], p. 123.

An equivalent formulation of the lemma is that for every $H \in H^+(p, \mathbb{R})$ and $F \in A(p, \mathbb{R})$ there exists $A \in GL(p, \mathbb{R})$ such that $AHA' = I_p$ and $AFA' = \Lambda$. This yields another equivalent formulation in terms of $2p \times 2p$ real matrices. For $T = \begin{pmatrix} H & 0 \\ 0 & H \end{pmatrix} \in H^+(p, \mathbb{R}) \otimes I_2$ and $R = \begin{pmatrix} 0 & -F \\ F & 0 \end{pmatrix} \in A(p, \mathbb{R}) \otimes J_1$, there exists $M = \begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix} \in GL(p, \mathbb{R}) \otimes I_2$ such that

(40) $MTM' = I_{2p}$ and $MRM' = \begin{pmatrix} 0 & -\Lambda \\ \Lambda & 0 \end{pmatrix}$.
It is seen from (40) that $\pm \lambda_1, \cdots, \pm \lambda_{[p/2]}$ are uniquely determined as the eigenvalues of $R$ w.r.t. $T$, each with multiplicity two. (When $p$ is odd 0 is always an eigenvalue with multiplicity two.)

For $T = t(S)$ and $R = S - t(S)$ it now follows that there exists an $M \in \text{GL}(p, \mathbb{R}) \otimes I_2$ such that

$$
(41) \quad \text{MSM}' = \begin{pmatrix}
I & -\Lambda \\
\Lambda & I_p \\
\end{pmatrix},
$$

and that (38) can be represented by

$$
(42) \quad \pi: H^+(p, \mathbb{C}) \to \Lambda_{[p/2]},
$$

where $\pi(S)$ is the ordered family of the nonnegative eigenvalues of $S - t(S)$ w.r.t. $t(S)$. As in section 2 it is seen that this representation is also topological.

**Theorem 2.** The maximum likelihood estimator of $\Sigma$ under $H_0$ is $t(S)$ and the likelihood ratio statistic for testing $H_0$ is

$$
(43) \quad \prod_{\gamma=1}^{[p/2]} \left(1 - \lambda_{\gamma}^2\right)^N,
$$

where $(\lambda_1, \cdots, \lambda_{[p/2]}) = \pi(S)$. Under the hypothesis $H_0$ the statistics $t(S)$ and $\pi(S)$ are independently distributed. The distribution of $t(S)$ has the density

$$
(44) \quad \frac{\left(\det T\right)^{N/2}}{\left(\det \Sigma\right)^{N/2}} \exp\left(-N/2 \text{ tr}(\Sigma^{-1}T), T \in H^+(p, \mathbb{R}) \otimes I_2\right).
$$
w.r.t. a unique measure \( \nu_{\mathbb{R},p,N} \) which is invariant under the action of \( \text{GL}(p, \mathbb{R}) \otimes \mathbb{I}_2 \) on \( H^+(p, \mathbb{R}) \otimes \mathbb{I}_2 \). The distribution of \( \Pi(S) \) has density (43) w.r.t. a measure \( \kappa \) on \( \Lambda_{[p/2]} \) which is uniquely defined by

\[
(t, \Pi)(\nu_{\mathbb{C},p,N}) = \nu'_{\mathbb{R},p,N} \otimes \kappa.
\]

Furthermore, \( \kappa \) has the density

(45)

\[
\prod_1^{\left(\lambda^2_\alpha - \lambda^2_\beta\right)^2} \prod_{\gamma=1}^{[p/2]} \lambda^2_y (1 - \lambda^2_y)^{-p},
\]

where \( \epsilon = p - 2[p/2] \), w.r.t. a Lebesgue measure on \( \Lambda_{[p/2]} \).

Remark. The maximum likelihood estimator of \( \Gamma \) under \( H_0 \) is \( H \).

Since the mapping \( T = \text{diag}(H, H) : H^+(p, \mathbb{R}) \otimes \mathbb{I}_2 \rightarrow H^+(p, \mathbb{R}) \) transforms \( \nu_{\mathbb{R},p,N} \) into \( \nu_{\mathbb{R},p,2N} \), it is seen from (44) that \( H \) is Wishart distributed with \( 2N \) degrees of freedom and parameter \( \frac{1}{2N} \).

Proof. If in section 2 one replaces \( \text{GL}(p, \mathbb{C}) \) by \( \text{GL}(p, \mathbb{R}) \otimes \mathbb{I}_2 \), \( H^+(2p, \mathbb{R}) \) by \( H^+(p, \mathbb{C}) \), \( H^+(p, \mathbb{C}) \) by \( H^+(p, \mathbb{R}) \otimes \mathbb{I}_2 \), \( S(p, \mathbb{C}) \) by \( \text{A}(p, \mathbb{R}) \otimes \mathbb{J}_1 \), \( \nu_{\mathbb{R},2p,N} \) by \( \nu_{\mathbb{C},p,N} \), \( \nu_{\mathbb{C},p,N} \) by \( \nu_{\mathbb{R},p,N} \) and \( (\lambda_1, \ldots, \lambda_p) \) by \( (\lambda_1, \ldots, \lambda_{[p/2]}) \), then the proof is completely analogous to the proof of Theorem 1 except for the following changes: The determinant of the right hand side of (41) is \( \prod_{\gamma=1}^{[p/2]} (1 - \lambda^2_y)^2 \) which gives (43). The invariant measure \( \nu_{\mathbb{C},p,N} \) has density \( |\det S|^{-p/2} \) w.r.t. a Lebesgue measure on \( H^+(p, \mathbb{C}) \) (Bourbaki [11], p. 93) which gives the factor \( \prod_{\gamma=1}^{[p/2]} (1 - \lambda^2_y)^{-p} \) in (45). Finally, we shall show below that the Jacobian of
\[ dR = \sum_{j=1}^{m} a_j \sum_{k=0}^{2j} R_k^0 (dR) R_0^{2j-k}, \]

where

\[ dR = \begin{pmatrix} 0 & -F \\ F & 0 \end{pmatrix} \in A(p, \mathbb{R}) \otimes J_1 \quad \text{and} \quad R_0 = \begin{pmatrix} 0 & -\Lambda \\ \Lambda & 0 \end{pmatrix}, \]

is

\[ (46) \prod_{\gamma=1}^{[p/2]} Dr(\lambda_{\gamma}) \prod_{1 \leq \alpha < \beta \leq [p/2]} \left[ \frac{r(\lambda_{\alpha})^2 - r(\lambda_{\beta})^2}{\lambda_{\alpha}^2 - \lambda_{\beta}^2} \right]^2 \prod_{\gamma=1}^{[p/2]} \left[ \frac{r(\lambda_{\gamma})}{\lambda_{\gamma}} \right]^{2c}, \]

when \( 1 > \lambda_1 > \cdots > \lambda_{[p/2]} > 0 \), which gives the remaining factors in (45).

To prove (46), first note that \( J_1^{2j+1} = (-1)^j J_1 \) implies

\[ \sum_{j=1}^{m} a_j \sum_{k=0}^{2j} \left( \begin{array}{cc} 0 & -\Lambda \\ \Lambda & 0 \end{array} \right)^k \begin{pmatrix} 0 & -F \\ F & 0 \end{pmatrix} \begin{pmatrix} 0 & -\Lambda \\ \Lambda & 0 \end{pmatrix}^{2j-k} = \begin{pmatrix} 0 & -F_0 \\ F_0 & 0 \end{pmatrix}, \]

where \( F_0 = \sum_{j=1}^{m} a_j (-1)^j \sum_{k=0}^{2j} \Lambda^k F \Lambda^{2j-k} \). Now partition \( F = (F_{\alpha,\beta}) \), where \( F_{\alpha,\beta} \) is \( 2 \times 2 \), \( 1 \leq \alpha, \beta \leq [p/2] \), and where if \( p \) is odd, \( F_{\gamma, [p/2]+1} \) is \( 2 \times 1 \), \( 1 \leq \gamma \leq [p/2] \). Then \( F_{\gamma, \gamma} \) for \( 1 \leq \gamma \leq [p/2] \) is of the form \( tJ_1 \) and is mapped into

\[ \sum_{j=1}^{m} a_j (-1)^j \sum_{k=0}^{2j} \left( \begin{array}{cc} 0 & -\lambda_{\gamma} \\ \lambda_{\gamma} & 0 \end{array} \right)^k \begin{pmatrix} 0 & -t \\ t & 0 \end{pmatrix} \begin{pmatrix} 0 & -\lambda_{\gamma} \\ \lambda_{\gamma} & 0 \end{pmatrix}^{2j-k} = \]

\[ \sum_{j=1}^{m} a_j \lambda_{\gamma}^{2j} (2j+1) \begin{pmatrix} 0 & -t \\ t & 0 \end{pmatrix} = Dr(\lambda_{\gamma}) \begin{pmatrix} 0 & -t \\ t & 0 \end{pmatrix}, \]

which gives the factor \( Dr(\lambda_{\gamma}) \) in (46). For \( 1 \leq \alpha < \beta \leq [p/2] \), \( F_{\alpha,\beta} = \begin{pmatrix} v \\ w \end{pmatrix} \) is
mapped into

\[ \sum_{j=1}^{m} a_j (-1)^j \sum_{k=0}^{j} \begin{pmatrix} 0 & -\lambda \alpha \\ \lambda \alpha & 0 \end{pmatrix}^{2k} \begin{pmatrix} v & s \\ w & u \end{pmatrix} \begin{pmatrix} 0 & -\lambda \beta \\ \lambda \beta & 0 \end{pmatrix}^{2j-2k} + \]

\[ \sum_{j=1}^{m} a_j (-1)^j \sum_{k=0}^{j-1} \begin{pmatrix} 0 & -\lambda \alpha \\ \lambda \alpha & 0 \end{pmatrix}^{2k+1} \begin{pmatrix} v & s \\ w & u \end{pmatrix} \begin{pmatrix} 0 & -\lambda \beta \\ \lambda \beta & 0 \end{pmatrix}^{2j-2k-1} \]

\[= \sum_{j=1}^{m} a_j \sum_{k=0}^{j} \begin{pmatrix} \lambda \alpha \lambda \beta^{2j-2k} \end{pmatrix} \begin{pmatrix} v & s \\ w & u \end{pmatrix} \]

\[= \sum_{j=1}^{m} \begin{pmatrix} a \lambda \alpha \lambda \beta^{2j-1} \end{pmatrix} \begin{pmatrix} -u & w \\ s & -v \end{pmatrix} = \]

\[ \begin{pmatrix} av + bu & as - bw \\ aw - bs & au + bv \end{pmatrix}, \]

where

\[ a = (\lambda \alpha r(\lambda \alpha) - \lambda \beta r(\lambda \beta)) / (\lambda \alpha^2 - \lambda \beta^2) \] and

\[ b = (\lambda \beta r(\lambda \alpha) - \lambda \alpha r(\lambda \beta)) / (\lambda \alpha^2 - \lambda \beta^2). \]

The determinant of this mapping is \((a^2 - b^2)^2 = [(r(\lambda \alpha)^2 - r(\lambda \beta)^2)/(\lambda \alpha^2 - \lambda \beta^2)]^2\),

which gives the \((a, b)\)th factor in (46). If \( p \) is odd then \( F_{\gamma, [p/2] + 1} \equiv (V_s)^{\gamma} \) is mapped into

\[ \sum_{j=1}^{m} a_j (-1)^j \begin{pmatrix} 0 & -\lambda \gamma \\ \lambda \gamma & 0 \end{pmatrix}^{2j} \begin{pmatrix} r \gamma \\ s \gamma \end{pmatrix} = \frac{r(\lambda \gamma)}{\lambda \gamma} \begin{pmatrix} r \gamma \\ s \gamma \end{pmatrix}, \]

which gives the factor \((r(\lambda \gamma)/\lambda \gamma)^{2e}\) in (46).
4. TESTING THE HYPOTHESIS THAT A COVARIANCE MATRIX WITH COMPLEX STRUCTURE HAS QUATERNION STRUCTURE.

Let $\mathbb{H}$ denote the division algebra over $\mathbb{R}$ of quaternions and let $1, i, j, k$ be a canonical basis; i.e., $i^2 = j^2 = k^2 = -1$, $ij = -ji = k$, $jk = -kj = i$ and $ki = -ik = j$. The conjugate of a quaternion $q = a + ib + jc + kd$ is denoted by $\bar{q} = a - ib - jc - kd$. Define the $\mathbb{R}$-linear map $\rho$ of $\mathbb{H}$ into $\mathbb{H}$ by $\rho(a + ib + jc + kd) = a + ib - jc + kd$. It is seen that $\rho$ is an involutive antiautomorphism of $\mathbb{H}$; i.e. $\rho(\rho(q)) = q$ and $\rho(q_1 q_2) = \rho(q_2) \rho(q_1)$ for $q, q_1, q_2 \in \mathbb{H}$. Moreover, the set $\{q \in \mathbb{H} | \rho(q) = q\} = \{a + jc | a, c \in \mathbb{R}\}$ is isomorphic to the field of complex numbers, so it is here denoted by $\mathbb{C}$. (More generally, it can be shown that there is a one to one correspondence between the embeddings of the field of complex numbers into $\mathbb{H}$ and the involutive antiautomorphisms of $\mathbb{H}$ other than the conjugation operator.)

Let $E$ be a $p$-dimensional right vector space over $\mathbb{H}$. Since $E$ is a right vector space the scalar multiplication of an $x \in E$ by $q \in \mathbb{H}$ is denoted $xq$. By restricting the scalar multiplication to the subalgebra of real numbers, $E$ is also a $4p$-dimensional vector space over $\mathbb{R}$, and if $e_1, \ldots, e_p$ is a basis for $E$ as a vector space over $\mathbb{H}$ then

\begin{equation}
(47) \quad e_1, \ldots, e_p, e_1i, \ldots, e_pi, e_1j, \ldots, e_pj, e_1k, \ldots, e_pk
\end{equation}

becomes a basis for $E$ as a vector space over $\mathbb{R}$.

If $f$ is an $\mathbb{H}$-linear map of $E$ into $E$ with matrix $A + iB_1 + jB_2 + kB_3$ w.r.t. $e_1, \ldots, e_p$ then $f$ considered as an $\mathbb{R}$-linear
map has matrix

\[
M = \begin{pmatrix}
A & -B_1 & -B_2 & -B_3 \\
B_1 & A & -B_3 & B_2 \\
B_2 & B_3 & A & -B_1 \\
B_3 & -B_2 & B_1 & A
\end{pmatrix}
\]

w.r.t. (47). Since composition of linear maps corresponds to multiplication of matrices it is seen that the set \( \text{GL}(p, \mathbb{H}) \) of all nonsingular \( 4p \times 4p \) matrices of the form (48) is a subgroup of \( \text{GL}(2p, \mathbb{C}) \).

Let \( \phi: E \times E \to \mathbb{H} \) be a hermitian left sesquilinear quaternion form on \( E \) (see [9] or [1]) with matrix \( \phi = C + iD_1 + jD_2 + kD_3 = (\phi(e_\alpha, e_\beta)). \) Then \( C \) is symmetric and \( D_1, D_2 \) and \( D_3 \) are antisymmetric. Moreover, \( \delta = \text{Re} \circ \phi, \) where \( \text{Re} \) denotes the real part of a quaternion, is a symmetric bilinear real form on \( E \) and the matrix of \( \delta \) w.r.t. (47) is

\[
\Delta = \begin{pmatrix}
C & -D_1 & -D_2 & -D_3 \\
D_1 & C & -D_3 & D_2 \\
D_2 & D_3 & C & -D_1 \\
D_3 & -D_2 & D_1 & C
\end{pmatrix}.
\]

The form \( \phi \circ (f \times f) \) is also hermitian left sesquilinear and the matrix of \( \text{Re} \circ (\phi \circ (f \times f)) = (\text{Re} \circ \phi) \circ (f \times f) \) w.r.t. (47) is

\[
\begin{pmatrix}
M' & \Delta & M
\end{pmatrix}.
\]

Since \( \phi \) is positive definite if and only if \( \text{Re} \circ \phi \) is positive definite it follows that the action

\[
\text{GL}(p, \mathbb{H}) \times H^+(p, \mathbb{H}) \to H^+(p, \mathbb{H})
\]

\[
(M, T) \mapsto MTM',
\]
where \( H^+(p, \mathbb{H}) \) is the set of positive definite matrices of the form (49), is well defined. It follows from the first equation in (59) below that this action is transitive. Moreover, since it is a restriction of the proper action (6) it is also proper. We remark that \( H^+(p, \mathbb{H}) \) is a subset of \( H^+(2p, \mathbb{C}) \).

Next let \( \phi: \mathbb{E} \times \mathbb{E} \to \mathbb{H} \) be a hermitian left \( \rho \)-sesquilinear quaternion form on \( \mathbb{E} \), i.e., \( \phi(xq_1, yq_2) = \rho(q_1) \phi(x, y)q_2 \), \( \phi(y, x) = \rho(\phi(x, y)) \), and \( \phi(x_1 + x_2, y) = \phi(x_1, y) + \phi(x_2, y) \), \( q_1, q_2 \in \mathbb{H}, y, x, x_1, x_2 \in \mathbb{E} \). If \( \phi = C + iD_1 + jD_2 + kD_3 = (\phi(e_{\alpha}, e_{\beta})) \) is the matrix of \( \phi \) then \( C, D_1, \) and \( D_3 \) are symmetric and \( D_2 \) is antisymmetric. Moreover, \( \delta \equiv \text{Re} \circ \phi \) is a symmetric bilinear real form on \( \mathbb{E} \), and the matrix of \( \delta \) w.r.t. (47) is

\[
\Xi = \begin{pmatrix}
C & -D_1 & -D_2 & -D_3 \\
-D_1 & C & D_3 & -D_2 \\
-D_2 & D_3 & C & -D_1 \\
-D_3 & D_2 & -D_1 & C
\end{pmatrix}.
\]

The form \( \phi \circ (f \times f) \) is also hermitian left \( \rho \)-sesquilinear and the matrix of \( \text{Re} \circ (\phi \circ (f \times f)) = (\text{Re} \circ \phi) \circ (f \times f) \) w.r.t. (47) is

\[
M' \Xi M \in S(p, \mathbb{H}),
\]

where \( S(p, \mathbb{H}) \) is the set of matrices of the form (52).

Let \( x_1, \ldots, x_N, N \geq 2p \), be i.i.d. observations from a normal distribution on \( \mathbb{R}^{4p} \) with mean vector 0 and unknown covariance matrix \( \Sigma \in H^+(2p, \mathbb{C}) \). As in section 3 one obtains as a minimal sufficient statistic an observation \( S \) from a complex Wishart
distribution on $H^+(2p, \mathbb{C})$ with $N$ degrees of freedom and parameter $\frac{1}{N} \Sigma$. This distribution has the density (19) (with $p$ replaced by $2p$) w.r.t. $\mathbb{C}, 2p, N$.

Let $H_0$ denote the hypothesis that $\Sigma \in H^+(p, \mathbb{H})$, i.e., that $\Sigma$ has quaternion structure. The statistical problem of testing $H_0$ is invariant under the restriction of the action (5) (with $p$ replaced by $2p$) to the subgroup $GL(p, \mathbb{H})$. The problem is to find a representation of the orbit projection

$$\Pi: H^+(2p, \mathbb{C}) \rightarrow H^+(2p, \mathbb{C}) / GL(p, \mathbb{H})$$

and, when $H$ is true, the distribution of $\Pi$.

Let

$$J = J_p = \begin{bmatrix} 0 & 0 & 0 & -I_p \\ 0 & 0 & I_p & 0 \\ 0 & -I_p & 0 & 0 \\ I_p & 0 & 0 & 0 \end{bmatrix}.$$

It is seen that the linear map

$$t: H^+(2p, \mathbb{C}) \rightarrow H^+(p, \mathbb{H})$$

$$S = \begin{bmatrix} H_{11} & H_{12} & -F_{11} & -F_{12} \\ H_{21} & H_{22} & -F_{21} & -F_{22} \\ F_{11} & F_{12} & H_{11} & H_{12} \\ F_{21} & F_{22} & H_{21} & H_{22} \end{bmatrix} + \frac{1}{2} \begin{bmatrix} H_{11}+H_{22} & H_{12}+H_{21} & -F_{11}+F_{22} & -F_{12}+F_{21} \\ H_{21}-H_{12} & H_{22}+H_{11} & -F_{21}+F_{12} & -F_{22}+F_{11} \\ F_{11}-F_{22} & F_{12}+F_{21} & H_{11}+H_{22} & H_{12}-H_{21} \\ F_{21}+F_{12} & F_{22}-F_{11} & H_{21}-H_{12} & H_{22}+H_{11} \end{bmatrix}$$

is well defined, because $t(S) = \frac{1}{2}(S + JSJ') \in H^+(p, \mathbb{H})$. Since $J$ is the matrix w.r.t. (47) for scalar multiplication by $k$, it follows that $J$ commutes with all matrices of the form (48), and thus also that $t$ commutes with the actions of $GL(p, \mathbb{H})$. Moreover, the residual
Lemma 8. Let $\phi$ be a positive definite hermitian left sesquilinear form on $E$ and $\psi$ a hermitian left $\rho$-sesquilinear form on $E$. Then there exists a basis for $E$ such that the matrices of $\phi$ and $\psi$ are $I_\rho$ and $A$, respectively, where $A$ is defined in Lemma 1.

Proof. (See Bourbaki [9], p. 120.) Since $\phi$ is positive definite there exists an additive map $u$ of $E$ into $E$ such that $\psi(x,y) = \phi(u(x),y)$, $x, y \in E$. For $q \in \mathbb{H}$, $\phi(u(xq),y) = \psi(xq,y) = \rho(q)\psi(x,y) = \rho(q)\phi(u(x),y) = \phi(u(x)\overline{\rho(q)},y)$. Hence

$$(58) \quad u(xq) = u(x)\overline{\rho(q)}, q \in \mathbb{H}, x \in E.$$ 

Moreover, $\phi(u(x),y) = \psi(x,y) = \rho(\psi(y,x)) = \rho(\phi(u(y),x))$, and it follows that the orthogonal complement w.r.t. $\phi$ of any $u$-invariant $\mathbb{H}$-subspace $S$ of $E$ (i.e., $u(S) \subseteq S$) is also $u$-invariant. $E$ is therefore a direct orthogonal sum of minimal $u$-invariant subspaces. Let $S$ be one of these subspaces. Since $\overline{\rho(q)} = q$ for $q \in \mathbb{C} = \{a+jc|a,c \in \mathbb{R}\}$, it follows from (58) that the restriction of $u$ to $S$ is a $\mathbb{C}$-linear map of $S$ into $S$, and it must have an eigenvector. Therefore there exists $\lambda \in \mathbb{C}$ and $x \in S$ such that $\phi(x,x) = 1$ and $u(x) = x\lambda$. Hence $u(x\mathbb{H}) \subseteq x\mathbb{H}$ and, since $x\mathbb{H} \subseteq S$, $S = x\mathbb{H}$. Since $\overline{\lambda\phi}(x,x) = \phi(x\lambda,x) = \phi(u(x),x) = \psi(x,x) = \rho(\psi(x,x)) = \rho(\phi(u(x),x)) = \rho(\overline{\lambda\phi}(x,x)) = \phi(x,x)\overline{\rho(\lambda)}$, it follows that $\rho(\overline{\lambda}) = \overline{\lambda}$, and, since $\lambda \in \mathbb{C}$, $\lambda \in \mathbb{R}$. This shows that there exists an
orthonormal basis $e_1, \ldots, e_p$ for $E$ and $\lambda_1, \ldots, \lambda_p \in \mathbb{R}$ such that $u(e_\alpha) = e_\alpha \lambda_\alpha$, $\alpha = 1, \ldots, p$; i.e. the matrix of $\phi$ is the identity matrix and the matrix of $\psi$ is $\text{diag}(\lambda_1, \ldots, \lambda_p)$. It can be assumed that each $\lambda_\alpha \geq 0$, for if $\lambda_\alpha < 0$ we can replace $e_\alpha$ by $e_\alpha^\top$ and thus replace $\lambda_\alpha$ by $-\lambda_\alpha > 0$.

Since the matrices of $\text{Re}\phi$ and $\text{Re}\psi$ transform according to (50) and (53), the lemma has an equivalent formulation in terms of $4p \times 4p$ real matrices. Let $T \in \mathcal{H}^+(p, \mathbb{H})$ and $R \in S(p, \mathbb{H})$. Then there exists an $M \in \text{GL}(p, \mathbb{H})$ such that

$$MTM^\top = I_{4p} \quad \text{and} \quad MRM^\top = \text{diag}(\Lambda, -\Lambda, \Lambda, -\Lambda).$$

It is seen from (59) that $\pm \lambda_1, \ldots, \pm \lambda_p$ are uniquely determined as the eigenvalues of $R$ w.r.t. $T$, each with multiplicity two.

For $T = t(S)$ and $R = S - t(S)$ it now follows that there exists an $M \in \text{GL}(p, \mathbb{H})$, such that

$$MSM^\top = \text{diag}(I_p + \Delta, I_p - \Delta, I_p + \Delta, I_p - \Delta)$$

and that (54) can be represented by

$$\Pi: H^+(2p, \mathbb{C}) \to \Delta_p,$$

where $\Pi(S)$ is the ordered family of non-negative eigenvalues of $S - t(S)$ w.r.t. $t(S)$. As in section 2 it is seen that this representation is also topological.

**Theorem 3.** The maximum likelihood estimator of $\Sigma$ under $H_0$ is $t(S)$ and the likelihood ratio statistic for testing $H_0$ is
Under the hypothesis $H_0$ the statistics $t(S)$ and $\Pi(S)$ are independently distributed. The distribution of $t(S)$ has the density

$$\left( \frac{\det T}{\det \Sigma} \right)^{N/2} \exp(-N/2 \text{tr}(\Sigma^{-1} T)), T \in H^+(p, \mathbb{H})$$

w.r.t. a unique measure $\nu_{\mathbb{H}, p, N}$ which is invariant under the action (51). The distribution of $\Pi(S)$ has density (62) w.r.t. a measure $\kappa$ on $\Lambda_p$ which is uniquely defined by

$$(t, \Pi)(\nu_{\mathbb{C}, 2p, N}) = \nu_{\mathbb{H}, p, N} \otimes \kappa.$$ 

Furthermore, $\kappa$ has the density

$$\prod_{1 \leq \alpha < \beta \leq p} \lambda^2_\alpha - \lambda^2_\beta \prod_{\gamma=1}^{p} \lambda^2_\gamma (1 - \lambda^2_\gamma)^{-2p}$$

w.r.t. a Lebesgue measure on $\Lambda_p$.

Remark. The distribution given by the density (63) is called the quaternion Wishart distribution with $N$ degrees of freedom and parameter $\frac{1}{N} \Sigma \in H^+(p, \mathbb{H})$.

Proof. If in Section 2 one replaces $GL(p, \mathbb{C})$ by $GL(p, \mathbb{H})$, $H^+(2p, \mathbb{R})$ by $H^+(2p, \mathbb{C})$, $H^+(p, \mathbb{C})$ by $H^+(p, \mathbb{H})$, $S(p, \mathbb{C})$ by $S(p, \mathbb{H})$, $\nu_{\mathbb{R}, 2p, N}$ by $\nu_{\mathbb{C}, 2p, N}$, and $\nu_{\mathbb{C}, p, N}$ by $\nu_{\mathbb{H}, p, N'}$, then the proof is completely analogous to the proof of Theorem 1 except for the following changes: The determinant of the right hand side of (60) is $\Pi(1 - \lambda^2_\gamma)^2$, which gives (62). The invariant measure $\nu_{\mathbb{C}, 2p, N}$ has density $|\det S|^{-2p/2}$.
w.r.t. a Lebesgue measure on $H^+(2p, \mathbb{C})$ (Bourbaki [11], p. 93) which gives the factor $\prod (1 - \lambda_j^2)^{-2p}$ in (65). Finally the Jacobian of
\[
dR = \sum_{j=1}^{m} a_j \sum_{k=0}^{2j} R_0^{k}(dR)R_0^{2j-k},
\]
where $dR$ has the form (52) and $R_0 = \text{diag}(\Lambda, -\Lambda, \Lambda, -\Lambda)$, is
\[
\prod_{\gamma=1}^{p} Dr(\lambda_\gamma)^2 \prod_{1 \leq \alpha < \beta \leq p} \left( \frac{r(\lambda_\alpha)^2 - r(\lambda_\beta)^2}{\lambda_\alpha^2 - \lambda_\beta^2} \right)^2
\]
when $1 > \lambda_1 > \ldots > \lambda_p > 0$, which gives the remaining factors in (65). The proof of (66) is analogous to the proof of (29).

5. TESTING THE HYPOTHESIS THAT A COVARIANCE MATRIX WITH QUATERNION STRUCTURE HAS COMPLEX STRUCTURE.

Let $E$ be as in Section 2, $f$ a $\mathbb{C}$-linear map of $E$ into $E$, $\phi:E \times E \to \mathbb{C}$ an antisymmetric bilinear complex form on $E$, and $C+iD = (\phi(e_\alpha, e_\beta))$ the matrix of $\phi$ w.r.t. $e_1, \ldots, e_p$. Then $C$ and $D$ are antisymmetric. Moreover $\text{Re} \circ \phi$ is an antisymmetric bilinear real form on $E$, the matrix of $\text{Re} \circ \phi$ w.r.t. (1) is given by (7), $\phi \circ (f \times f)$ is also antisymmetric bilinear, and the matrix of $\text{Re} \circ (\phi \circ (f \times f)) = (\text{Re} \circ \phi) \circ (f \times f)$ w.r.t. (1) is given by
\[
\begin{pmatrix}
A & -B \\
B & A
\end{pmatrix}
\begin{pmatrix}
C & -D \\
-D & C
\end{pmatrix}
\begin{pmatrix}
A & -B \\
B & A
\end{pmatrix} \in A(p, \mathbb{C}),
\]
where $A(p, \mathbb{C})$ is the set of all antisymmetric matrices of the form (7).
Let $x_1, \ldots, x_N, N \geq p$, be i.i.d. observations from a normal distribution on $\mathbb{R}^{4p}$ with mean vector $0$ and unknown covariance matrix

$$
\Sigma = \begin{pmatrix}
\Gamma & -\Psi_1 & -\Psi_2 & -\Psi_3 \\
-\Psi_1 & \Gamma & -\Psi_3 & \Psi_2 \\
-\Psi_2 & \Psi_3 & \Gamma & -\Psi_1 \\
-\Psi_3 & -\Psi_2 & \Psi_1 & \Gamma \\
\end{pmatrix}.
$$

It follows from Sections 2 and 3 that the empirical covariance matrix transformed by the mappings (12) (with $p$ replaced by $2p$) followed by (56) is a minimal sufficient statistic, which follows a quaternion Wishart distribution with $N$ degrees of freedom and parameter $\frac{1}{N} \Sigma$. This distribution has the density (63) w.r.t. $\nu_{\mathbb{H}, p, N}$.

For $p > 1$ we shall consider the hypothesis $H_0$ that $\Psi_2 = \Psi_3 = 0$, i.e., that $\Sigma$ has a complex structure. The statistical problem of testing $H_0$ is invariant under the restriction of the action (51) to the subgroup $GL(p, \mathbb{C}) \otimes I_2 = \{ \text{diag}(A, A) | A \in GL(p, \mathbb{C}) \}$ of $GL(p, \mathbb{H})$. The problem is to find a representation of the orbit projection

$$
\Pi : H^+(p, \mathbb{H}) \rightarrow H^+(p, \mathbb{H}) / GL(p, \mathbb{C}) \otimes I_2
$$

and, when $H_0$ is true, the distribution of $\Pi$.

The group $GL(p, \mathbb{C}) \otimes I_2$ acts on $H^+(p, \mathbb{C}) \otimes I_2 \equiv \{ \text{diag}(H, H) | H \in H^+(p, \mathbb{C}) \}$ by restriction of (51). The linear map

$$
t : H^+(p, \mathbb{H}) \rightarrow H^+(p, \mathbb{C}) \otimes I_2
$$

$$
S = \begin{pmatrix}
H & -F \\
F & H
\end{pmatrix} \rightarrow \begin{pmatrix}
H & 0 \\
0 & H
\end{pmatrix}
$$
commutes with the actions of $\text{GL}(p, \mathbb{C}) \otimes I_2$, and the residual

$$S - t(S) = \begin{pmatrix} 0 & -F \\ F & 0 \end{pmatrix} \in A(p, \mathbb{C}) \otimes J_1,$$

where

$$A(p, \mathbb{C}) \otimes J_1 = \left\{ \begin{pmatrix} 0 & -F \\ F & 0 \end{pmatrix} \mid F \in A(p, \mathbb{C}) \right\}.$$

**Lemma 9.** Let $\phi$ be a positive definite hermitian left sesquilinear complex form and $\psi$ an antisymmetric bilinear complex form on a $p$-dimensional complex vector space. Then there exists a basis such that the matrices for $\phi$ and $\psi$ are $I_p$ and $\Lambda$ respectively, where $\Lambda$ is defined in (39).

**Proof.** Bourbaki [9], p. 123.

Since the matrices for $\text{Re} \circ \phi$ and $\text{Re} \circ \psi$ transform according to (4) and (67), respectively, an equivalent formulation of the lemma is that for every $H \in H^+(p, \mathbb{C})$ and $F \in A(p, \mathbb{C})$, there exists $A \in \text{GL}(p, \mathbb{C})$ such that $AHA' = I_p$ and $AFA' = \Lambda$. This can be reformulated in terms of $4p \times 4p$ real matrices. For

$$T \equiv \begin{pmatrix} H & 0 \\ 0 & H \end{pmatrix} \in H^+(p, \mathbb{C}) \otimes I_2 \quad \text{and} \quad R \equiv \begin{pmatrix} 0 & -F \\ F & 0 \end{pmatrix} \in A(p, \mathbb{C}) \otimes J_1,$$

there exists

$$M \equiv \begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix} \in \text{GL}(p, \mathbb{C}) \otimes I_2$$

such that

$$\text{(69)} \quad MTM' = I_{4p} \quad \text{and} \quad MRM' = \begin{pmatrix} 0 & 0 & -\Lambda & 0 \\ 0 & 0 & 0 & \Lambda \\ -\Lambda & 0 & 0 & 0 \\ 0 & -\Lambda & 0 & 0 \end{pmatrix}.$$
It is seen from (69) that \( \pm \lambda_2, \ldots, \pm \lambda_{[p/2]} \) are uniquely determined as the eigenvalues of \( R \) w.r.t. \( T \), each with multiplicity four. (When \( p \) is odd \( 0 \) is always an eigenvalue with multiplicity four.)

For \( T = t(S) \) and \( R = S - t(S) \) it now follows that there exists an \( M \in \text{GL}(p, \mathbb{C}) \otimes I_2 \) such that

\[
(70) \quad \text{MSM}' = \begin{pmatrix}
I_p & 0 & -\Lambda & 0 \\
0 & I_p & 0 & \Lambda \\
\Lambda & 0 & I_p & 0 \\
0 & -\Lambda & 0 & I_p \\
\end{pmatrix}
\]

and that (68) can be represented by

\[
(71) \quad \Pi : H^+(p, \mathbb{H}) \to \Lambda_{[p/2]},
\]

where \( \Pi(S) \) is the ordered family of non-negative eigenvalues of \( S - t(S) \) w.r.t. \( t(S) \). As in section 2 it is seen that this representation is also topological.

**Theorem 4.** The maximum likelihood estimator of \( \Sigma \) under \( H_0 \) is \( t(S) \) and the likelihood ratio statistic for testing \( H_0 \) is

\[
(72) \quad \prod_{\gamma=1}^{[p/2]} (1 - \lambda_\gamma^2)^2N,
\]

where \( (\lambda_1, \ldots, \lambda_{[p/2]}) = \Pi(S) \). Under the hypothesis \( H_0 \) the statistics \( t(S) \) and \( \Pi(S) \) are independently distributed. The distribution of \( t(S) \) has the density

\[
(73) \quad \left( \frac{\det T}{\det \Sigma} \right)^{N/2} \exp(-N/2 \text{tr}(\Sigma^{-1} T)), \quad T \in H^+(2p, \mathbb{C}) \otimes I_2
\]
w.r.t. a unique measure \( \nu'_{\mathcal{C},p,N} \) which is invariant under the action of \( \text{GL}(p, \mathbb{C}) \otimes I_2 \) on \( H^+(p, \mathbb{C}) \otimes I_2 \). The distribution of \( \Pi(S) \) has density (72) w.r.t. a measure \( \kappa \) on \( \Lambda_{[p/2]} \) which is uniquely defined by

\[
(t, \Pi)(\nu_{\mathcal{H},p,N}) = \nu'_{\mathcal{C},p,N} \otimes \kappa.
\]

Furthermore, \( \kappa \) has the density

\[
\prod_{1 \leq \alpha < \beta \leq p} (\lambda^2 - \lambda^2_{\beta})^4 \prod_{\gamma=1}^{\lceil p/2 \rceil} \lambda^4_{\gamma} (1 - \lambda^2_{\gamma})^{-2p+1},
\]

where \( \varepsilon = p - 2[p/2] \), w.r.t. a Lebesgue measure on \( \Lambda_{[p/2]} \).

**Remark.** The maximum likelihood estimator of \( \left( \frac{\text{I}}{\mathcal{I}_1} \right) \) under \( H_0 \) is \( \text{H} \).

Since the mapping \( T = \text{diag}(H,H) \to H \) from \( H^+(p, \mathbb{C}) \otimes I_2 \) onto \( H^+(p, \mathbb{C}) \)
transforms \( \nu'_{\mathcal{C},p,N} \) into \( \nu_{\mathcal{C},p,2N} \) it is seen from (73) that \( H \) follows a complex Wishart distribution with \( 2N \) degrees of freedom and parameter \( \frac{1}{2N} \left( \frac{\text{I}}{\mathcal{I}_1} \right) \).

**Proof.** If in section 2 one replaces \( \text{GL}(p, \mathbb{C}) \) by \( \text{GL}(p, \mathbb{C}) \otimes I_2 \),
\( H^+(2p, \mathbb{R}) \) by \( H^+(p, \mathbb{H}) \), \( H^+(p, \mathbb{C}) \) by \( H^+(p, \mathbb{C}) \otimes I_2 \), \( S(p, \mathbb{C}) \) by \( A(p, \mathbb{C}) \otimes J_1 \), \( \nu_{\mathbb{R},2p,N} \) by \( \nu_{\mathbb{H},p,N} \), \( \nu_{\mathbb{C},p,N} \) by \( \nu'_{\mathbb{C},p,N} \) and \( (\lambda_1, \ldots, \lambda_p) \) by \( (\lambda_1, \ldots, \lambda_{[p/2]}) \) then the proof is completely analogous to the proof of Theorem 1 except for the following changes: The determinant of the right hand side of (70) is \( \Pi(1-\lambda^2_{\gamma})^4 \), which gives (72). The invariant measure \( \nu_{\mathbb{H},p,N} \) has density \( |\det S|^{-\left( p - \frac{1}{2} \right) / 2} \) w.r.t. a Lebesgue measure on \( H^+(p, \mathbb{H}) \) (Bourbaki [11], p. 93) which gives the factor \( \Pi(1-\lambda^2_{\gamma})^{-2p+1} \) in (74). Finally the Jacobian of

\[
dR = \sum_{j=1}^{m} a_j \sum_{k=0}^{2j} R^k_0 (dR) R^{2j-k}_0,
\]
where

\[
\begin{pmatrix}
0 & 0 & -C & D \\
0 & 0 & D & C \\
C & -D & 0 & 0 \\
-D & C & 0 & 0
\end{pmatrix} \epsilon A(p, \mathcal{C}) \otimes J_1 \quad \text{and} \quad R_0 = \begin{pmatrix}
0 & 0 & -\Lambda & 0 \\
0 & 0 & 0 & \Lambda \\
\Lambda & 0 & 0 & 0 \\
0 & -\Lambda & 0 & 0
\end{pmatrix},
\]

is

\[
\prod_{\gamma=1}^{[p/2]} \frac{\text{Dr}(\lambda_\gamma)}{\lambda_\gamma} \prod_{1 \leq \alpha < \beta \leq p} \frac{r(\lambda_\alpha)^2 - r(\lambda_\beta)^2}{\lambda_\alpha^2 - \lambda_\beta^2} \prod_{\gamma=1}^{[p/2]} \left( \frac{r(\lambda_\gamma)}{\lambda_\gamma} \right)^{4e}
\]

when \( 1 > \lambda_1 > ... > \lambda_{[p/2]} > 0 \), which gives the remaining factors in (74).

The proof of (75) is completely analogous to the proof of (46).

6. TESTING INDEPENDENCE OF TWO SETS OF VARIATES WHERE THE SIMULTANEOUS COVARIANCE MATRIX HAS REAL, COMPLEX, OR QUATERNION STRUCTURE.

Let \( \mathbb{D} \) denote \( \mathbb{R}, \mathbb{C}, \) or \( \mathbb{H} \) and set \( \delta = \dim_{\mathbb{R}} \mathbb{D} \), i.e., \( \delta = 1, 2, \) or 4.

Let \( M(p_2, p_1, \mathbb{D}) \) denote the set of all \( p_2 \times p_1 \) real matrices when \( \mathbb{D} = \mathbb{R} \); the set of all \( 2p_2 \times 2p_1 \) real matrices of the form (2), where \( A \) and \( B \) are \( p_2 \times p_1 \) matrices, when \( \mathbb{D} = \mathbb{C} \); and the set of all \( 4p_2 \times 4p_1 \) real matrices of the form (48), where \( A, B_1, B_2, \) and \( B_3 \) are \( p_2 \times p_1 \) matrices, when \( \mathbb{D} = \mathbb{H} \). Let \( E_1 \) and \( E_2 \) be right vector spaces over \( \mathbb{D} \) of dimensions \( p_1 \) and \( p_2 \), respectively, \( g: E_1 \rightarrow E_2 \) a \( \mathbb{D} \)-linear map, and \( \psi: E_2 \times E_1 + \mathbb{D} \) a left sesquilinear \( \mathbb{D} \)-form. The \( \delta p_2 \times \delta p_1 \) real matrices of \( g \) and \( \Re \circ \psi \) w.r.t. bases for \( E_1 \) and \( E_2 \) considered as vector spaces over \( \mathbb{R} \) are both of the form (2) when \( \mathbb{D} = \mathbb{C} \) and of the form (48) when \( \mathbb{D} = \mathbb{H} \), hence belong to \( M(p_2, p_1, \mathbb{D}) \). If \( f_1: E_1 \rightarrow E_1 \) and \( f_2: E_2 \rightarrow E_2 \) are \( \mathbb{D} \)-linear maps, then \( \psi \circ (f_2 \times f_1) \) is a left sesquilinear \( \mathbb{D} \)-form, and
since \( \text{Re} \circ (\psi \circ (f_2 \times f_1)) = (\text{Re} \circ \psi) \circ (f_2 \times f_1) \), it is seen that

\[
M_2 \psi M_1^t \in M(p_2, p_1, \mathcal{D})
\]

for \( M_1 \in \text{GL}(p_1, \mathcal{D}) \), \( M_2 \in \text{GL}(p_2, \mathcal{D}) \), and \( \psi \in M(p_2, p_1, \mathcal{D}) \).

Let \( x \) be an observation from a normal distribution on \( \mathbb{R}^{\delta p} \) with covariance matrix \( \Sigma \in \mathcal{H}^+(p, \mathcal{D}) \) and let \( p = p_1 + p_2 \) with \( 0 < p_2 \leq p_1 \).

Partition \( x \) into \( \delta \) p-dimensional subvectors \( x_\alpha \), \( \alpha = 1, \ldots, \delta \), corresponding to the partition of \( \Sigma \) into \( p \times p \) submatrices given by its "\( \mathcal{D} \)-structure" (see (3) and (49)). Furthermore, partition each \( x_\alpha \) into \( x^1_\alpha \) and \( x^2_\alpha \) consisting of the first \( p_1 \) and the last \( p_2 \) coordinates of \( x_\alpha \), respectively, \( \alpha = 1, \ldots, \delta \). Permuting these \( 2\delta \) subvectors into the order \( x^1_1, \ldots, x^1_\delta, x^2_1, \ldots, x^2_\delta \), one transforms \( \Sigma \) into the form

\[
\Sigma = \begin{pmatrix}
\Sigma_{11} & \Sigma_{12} \\
\Sigma_{21} & \Sigma_{22}
\end{pmatrix},
\]

where \( \Sigma_{11} \in \mathcal{H}^+(p_1, \mathcal{D}) \), \( \Sigma_{22} \in \mathcal{H}^+(p_2, \mathcal{D}) \), \( \Sigma_{21} \in M(p_2, p_1, \mathcal{D}) \), and \( \Sigma_{12} = \Sigma_{21}^t \). The set of positive definite matrices of the form (76) is here denoted \( \mathcal{H}^+(p_1, p_2, \mathcal{D}) \). We shall discuss the problem of testing the independence of \( (x^1_1, \ldots, x^1_\delta) \) and \( (x^2_1, \ldots, x^2_\delta) \).

Let \( x_1, \ldots, x_N, N \geq p > 1 \), be i.i.d. observations from a normal distribution on \( \mathbb{R}^{\delta p} \) with mean vector \( 0 \) and unknown covariance matrix \( \Sigma \in \mathcal{H}^+(p_1, p_2, \mathcal{D}) \). The maximum likelihood estimate \( S \) of \( \Sigma \) also has the form (76),

\[
S = \begin{pmatrix}
S_{11} & S_{12} \\
S_{21} & S_{22}
\end{pmatrix},
\]

and it follows from the preceding sections that \( S \) is \( \mathcal{D} \)-Wishart distributed.
with \( N \) degrees of freedom and parameter \( \frac{1}{N} \).

The statistical problem under consideration is that of testing the hypothesis \( H_0 \) that \( \Sigma_{12} = \Sigma_{21} = 0 \). This problem is invariant under the action

\[
GL(p_1, \mathbb{D}) \oplus GL(p_2, \mathbb{D}) \times H^+(p_1, p_2, \mathbb{D}) \to H^+(p_1, p_2, \mathbb{D})
\]

\((77)\)

\[
\begin{pmatrix}
M_1 & 0 \\
0 & M_2
\end{pmatrix},
\begin{pmatrix}
S_{11} & S_{12} \\
S_{21} & S_{22}
\end{pmatrix}
\to
\begin{pmatrix}
M_1 S_{12} M_1^t & M_1 S_{12} M_2^t \\
M_2 S_{21} M_1^t & M_2 S_{22} M_2^t
\end{pmatrix},
\]

where \( GL(p_1, \mathbb{D}) \oplus GL(p_2, \mathbb{D}) = \{ \text{diag}(M_1, M_2) | M_1 \in GL(p_1, \mathbb{D}), M_2 \in GL(p_2, \mathbb{D}) \} \).

If one permutes the coordinates as above it is seen that

\( GL(p_1, \mathbb{D}) \oplus GL(p_2, \mathbb{D}) \) becomes a subgroup of \( GL(p_1 + p_2, \mathbb{D}) \) and thus \((77)\) is a restriction of the actions \((6), (5), \) or \((51)\) in the cases \( \mathbb{D} = \mathbb{R}, \mathbb{C}, \) or \( \mathbb{H} \), respectively.

The linear map

\[
t: H^+(p_1, p_2, \mathbb{D}) \to H^+(p_1, \mathbb{D}) \oplus H^+(p_2, \mathbb{D})
\]

\[
S = \begin{pmatrix}
S_{11} & S_{12} \\
S_{21} & S_{22}
\end{pmatrix} \to \begin{pmatrix}
S_{11} & 0 \\
0 & S_{22}
\end{pmatrix}
\]

commutes with the action \((77)\) and the transitive action

\[
GL(p_1, \mathbb{D}) \oplus GL(p_2, \mathbb{D}) \times H^+(p_1, \mathbb{D}) \oplus H^+(p_2, \mathbb{D}) \to H^+(p_1, \mathbb{D}) \oplus H^+(p_2, \mathbb{D})
\]

\((78)\)

\[
(M, T) \to MTM',
\]

where \( H^+(p_1, \mathbb{D}) \oplus H^+(p_2, \mathbb{D}) = \{ \text{diag}(\Sigma_1, \Sigma_2) | \Sigma_1 \in H^+(p_1, \mathbb{D}), \Sigma_2 \in H^+(p_2, \mathbb{D}) \} \).

**Lemma 10.** Let \( \phi_1: E_1 \times E_1 \to \mathbb{D} \) and \( \phi_2: E_2 \times E_2 \to \mathbb{D} \) be positive definite hermitian left sesquilinear forms and \( g: E_2 \to E_1 \) a \( \mathbb{D} \)-linear map. Then there exist
\( \mathbb{D} \)-bases of \( E_1 \) and \( E_2 \) such that the matrices of \( \phi_1 \) and \( \phi_2 \) are
\[
\begin{pmatrix}
I \\
P_1 \\
I \\
P_2
\end{pmatrix}
\]
respectively, and the matrix of \( g \) is
\[
\Lambda = \begin{pmatrix}
\lambda_1 & \cdots & 0 \\
\vdots & \ddots & \vdots \\
0 & \cdots & \lambda_{P_2}
\end{pmatrix},
\]
where \( \lambda_1 \geq \ldots \geq \lambda_{P_2} \geq 0 \).

Proof. It follows from Lemma 11 in the next section that there exists a basis \( f_1, \ldots, f_{P_2} \) of \( E_2 \) such that the matrix of \( \phi_2 \) is \( I \) and the matrix of \( \phi_1 \circ (g \times g) \) is \( \text{diag}(\lambda_1^2, \ldots, \lambda_{P_2}^2) \), where \( \lambda_1 \geq \ldots \geq \lambda_{P_2} \geq 0 \). Set \( e_i = g(f_i) \lambda_i^{-1} \) for \( \lambda_i > 0 \); these \( e_i \)'s are orthonormal w.r.t. \( \phi_1 \) and they can therefore be extended to a basis \( e_1, \ldots, e_{P_1} \) for \( E_1 \) which is orthonormal w.r.t. \( \phi_1 \), i.e., the matrix of \( \phi_1 \) is \( I_{P_1} \). Since \( g(f_i) = e_i \lambda_i \), \( i = 1, \ldots, P_2 \), the lemma follows.

In terms of real matrices the lemma states that for \( \phi_1 \in \mathcal{H}^+(P_1, \mathbb{D}) \), \( \phi_2 \in \mathcal{H}^+(P_2, \mathbb{D}) \), and \( G \in M(P_2, P_1, \mathbb{D}) \), there exists an \( A_1 \in \text{GL}(P_1, \mathbb{D}) \) and an \( A_2 \in \text{GL}(P_2, \mathbb{D}) \) such that \( A_1 \phi_1 A_1^\dagger = I_{P_1} \otimes I_\delta \), \( A_2 \phi_2 A_2^\dagger = I_{P_2} \otimes I_\delta \), and \((A_2^\dagger)^{-1} G A_1^\dagger = \Lambda \otimes I_\delta \).

For \( \phi_1 = S_{11} \), \( \phi_2 = S_{22}^{-1} \), \( G = S_{21} \), \( M_1 = A_1 \), and \( M_2 = (A_2^\dagger)^{-1} \), one obtains that there exists an \( M \in \text{GL}(P, \mathbb{D}) \otimes \text{GL}(P, \mathbb{D}) \) such that
\[
(79) \quad \text{MSM}' = \begin{pmatrix}
I_{P_1} \otimes I_\delta & \Lambda' \otimes I_\delta \\
\Lambda \otimes I_\delta & I_{P_2} \otimes I_\delta
\end{pmatrix}.
\]

Hence the orbit projection corresponding to the action (77) can be represented by
\[ \Pi : H^+(p_1, p_2, D) \to \Lambda_{p_2}, \]

where \( \Pi(S) \) is the ordered family of the first \( p_2 \) non-negative eigenvalues of \( S - t(S) \) w.r.t. \( t(S) \) each with multiplicity \( \delta \). (0 is always an eigenvalue with multiplicity at least \( \delta(p_1 - p_2) \)).

**Theorem 5.** The maximum likelihood estimator of \( \Sigma \) under \( H_0 \) is \( t(S) \) and the likelihood ratio statistic for testing \( H_0 \) is

\[ (80) \quad \frac{p_2}{\prod_{\gamma=1}^{\lambda} (1 - \lambda_{\gamma}^2)^{\delta/2}} \exp(-N/2 \text{ tr } (\Sigma^{-1} S)), S \in H^+(p_1, D) \Theta H^+(p_2, D) \]

where \( (\lambda_1, \ldots, \lambda_{p_2}) = \Pi(S) \). Under the hypothesis \( H_0 \) the statistics \( t(S) \) and \( \Pi(S) \) are independently distributed. The distribution of \( t(S) \) has density

\[ (81) \quad \left( \frac{\det T}{\det \Sigma} \right)^{N/2} \exp(-N/2 \text{ tr } (\Sigma^{-1} S)), S \in H^+(p_1, D) \Theta H^+(p_2, D) \]

w.r.t. a unique measure \( \nu_{D, p_1, N} \otimes \nu_{D, p_2, N} \) which is invariant under the action of \( \text{GL}(p_1, D) \Theta \text{GL}(p_2, D) \) on \( H^+(p_1, D) \Theta H^+(p_2, D) \). The distribution of \( \Pi(S) \) has density (80) w.r.t. a measure \( \kappa \) on \( \Lambda_{p_2} \) which is uniquely defined by

\[ (t, \Pi)(\nu_{D, p, N}) = (\nu_{D, p_1, N} \otimes \nu_{D, p_2, N}) \otimes \kappa. \]

Furthermore, \( \kappa \) has density

\[ (82) \quad \frac{p_2}{\prod_{\gamma=1}^{\lambda} (1 - \lambda_{\gamma}^2)^{\delta/2}} \left( p - 1 + \frac{2}{\delta} \right)^{\delta(p_1 - p_2) + \delta - 1} \prod_{1 \leq \alpha < \beta \leq p_2} (\lambda_{\alpha}^2 - \lambda_{\beta}^2)^{\delta} \]

w.r.t. a Lebesgue measure on \( \Lambda_{p_2} \).
Remark. The maximum likelihood estimators for $\Sigma_{11}$ and $\Sigma_{22}$ are $S_{11}$ and $S_{22}$, respectively, and it is seen from (81) that these are independently distributed and that $S_{1i}$ follows a $\mathbb{D}$-Wishart distribution with $N$ degrees of freedom and parameter $\frac{1}{N} \Sigma_{ii}$, $i = 1, 2$.

Proof. The proof is analogous to the proof of Theorem 1. The determinant of (79) is $\Pi (1- \lambda^2_\gamma) \delta$, which gives (80). The invariant measure $\nu_{\mathbb{D}, p, N}$ on $H^+(p, \mathbb{D})$ has density $|\det S|^{-2(p-1+\delta)/2}$ w.r.t. a Lebesgue measure, and that gives the first factor in (82). The Jacobian of

$$\text{(83)} \quad dR = \sum_{j=1}^{m} a_j \sum_{k=0}^{2j} R_0^k (dR) R_0^{2j-k},$$

where $dR = \begin{pmatrix} O & G^t \\ G & O \end{pmatrix}$, $G \in M(p_1, p_2, \mathbb{D})$ and $R_0 = \begin{pmatrix} O & \Lambda \otimes I_\delta \\ \Lambda' \otimes I_\delta & O \end{pmatrix}$, is

$$\text{(84)} \quad \prod_{\gamma=1}^{p_2} Dr(\lambda_\gamma) \left( \frac{r(\lambda_\gamma)}{\lambda_\gamma} \right)^{\delta-1+\delta(p_1-p_2)} \prod_{1 \leq \alpha < \beta \leq p_2} \left( \frac{r(\lambda_\alpha)}{\lambda_\alpha} - \frac{r(\lambda_\beta)}{\lambda_\beta} \right)^\delta$$

when $1 > \lambda_1 > \ldots > \lambda_{p_2} > 0$, which gives the remaining factors in (82).

We shall indicate the proof of (84) in the case $\mathbb{D} = \mathbb{H}$: Recall that $G$ is of the form (48). Under the mapping (83) the $(\gamma, \gamma)'$th element of $A$ is multiplied by $Dr(\lambda_\gamma)$, the $(\gamma, \gamma)'$th elements of $B_1, B_2, B_3$ are multiplied by $r(\lambda_\gamma)/\lambda_\gamma$, and for $\beta > p_2$ the $(\gamma, \beta)'$th elements of $A, B_1, B_2, B_3$ are multiplied by $r(\lambda_\gamma)/\lambda_\gamma$. For $1 \leq \alpha < \beta \leq p_2$ the pair of elements $(t_{\alpha\beta}, t_{\beta\alpha})$ of $A, B_1, B_2, B_3$ are mapped into the pair $(at_{\alpha\beta} + bt_{\beta\alpha}, at_{\beta\alpha} + bt_{\alpha\beta})$, where $a$ and $b$ are as in the proof of Theorem 2; this mapping has the determinant

$$(a^2 - b^2)^\delta = \left[ (r(\lambda_\alpha)^2 - r(\lambda_\beta)^2)/(\lambda_\alpha^2 - \lambda_\beta^2) \right]^\delta.$$
7. TESTING THE HYPOTHESIS THAT TWO COVARIANCE MATRICES WITH REAL, COMPLEX, OR QUATERNION STRUCTURE ARE IDENTICAL.

As in section 6 we denote by $\mathcal{D}$ either $\mathbb{R}$, $\mathbb{C}$, or $\mathbb{H}$, and $\delta = \text{dim}_\mathbb{R}\mathcal{D}$. Let $S_1$ and $S_2$ be independent observations from $\mathcal{D}$- Wishart distributions with $N_1$ and $N_2$ degrees of freedom and parameters $\Sigma_1, \Sigma_2 \in H^+(p, \mathcal{D})$ respectively, $p \leq N_1$ and $p \leq N_2$. Since $\nu_{\mathcal{D}, p, \mathcal{D}}$ is invariant and $\det(\Sigma S) = N^\delta \det(\Sigma)$ for $\Sigma \in H^+(p, \mathcal{D})$, it follows from the preceding sections that the distribution of $(S_1, S_2)$ has density

$$\frac{(\det S_1)^{N_1/2}(\det S_2)^{N_2/2}}{(\det S_1)(\det S_2)} \exp(-\frac{1}{2} \text{tr}(\Sigma_1^{-1}S_1 + \Sigma_2^{-1}S_2)), (S_1, S_2) \in H^+(p, \mathcal{D})^2$$

w.r.t. $\nu_{\mathcal{D}, p, \mathcal{D}}, \nu_{\mathcal{D}, p, \mathcal{D}}^0$, where $\nu_{\mathcal{D}, p, \mathcal{D}}^0 = (1/N_i)^\delta N_i^{1/2} \nu_{\mathcal{D}, p, \mathcal{D}}, p \leq N_i, i=1,2$.

Let $H_0$ denote the hypothesis that $\Sigma_1 = \Sigma_2$. The statistical problem of testing $H_0$ is invariant under the action

$$(\text{GL}(p, \mathcal{D}) \times H^+(p, \mathcal{D})^2 \twoheadrightarrow H^+(p, \mathcal{D})^2$$

$$(M, (S_1, S_2)) \rightarrow (MS_1M', M S_2M').$$

The linear map

$$t:H^+(p, \mathcal{D})^2 \rightarrow H^+(p, \mathcal{D})$$

$$(S_1, S_2) \rightarrow S_1 + S_2$$

commutes with the actions (85) and (6), (5), or (51), respectively.

**Lemma 11.** Let $\phi$ be a positive definite hermitian left sesquilinear $\mathcal{D}$-form and $\psi$ a hermitian left sesquilinear $\mathcal{D}$-form on a $p$-dimensional
vector space over $\mathbb{D}$. Then there exists a basis such that the matrix of $\phi$ is $I_p$ and the matrix of $\psi$ is $\Lambda = \text{diag}(\lambda_1, \ldots, \lambda_p)$, where $\lambda_1 \geq \cdots \geq \lambda_p$.

Proof. Bourbaki [9], p. 123.

In terms of $p \times p$ real matrices the lemma implies that there exists an $M \in \text{GL}(p, \mathbb{D})$ such that $M(S_1 + S_2)M' = I_p$, and $MS_1M' = \Lambda \otimes I_p$. Then $MS_2M' = (I - \Lambda) \otimes I_p$, and it is seen that the orbit projection corresponding to the action (85) can be represented by

$$\Pi: H^+(p, \mathbb{D})^2 \rightarrow \Lambda_p,$$

where $\Pi(S_1, S_2) = (\lambda_1, \ldots, \lambda_p)$ and $1 > \lambda_1 \geq \cdots \geq \lambda_p > 0$ are the eigenvalues of $S_1$ w.r.t. $S_1 + S_2$, each with multiplicity $\delta$.

**Theorem 6.** The maximum likelihood estimator for $\Sigma$ (the common value of $\Sigma_1$ and $\Sigma_2$) under $H_0$ is $\frac{1}{N_1 + N_2} t(S_1, S_2)$ and the likelihood ratio test statistic for testing $H_0$ is

$$\prod_{\gamma=1}^{\Sigma} \frac{\delta N_1/2}{(1 - \lambda_\gamma) \delta N_2/2},$$

where $(\lambda_1, \ldots, \lambda_p) = \Pi(S_1, S_2)$. Under the hypothesis $H_0$ the statistics $t(S_1, S_2)$ and $\Pi(S_1, S_2)$ are independently distributed. The distribution of $t(S_1, S_2)$ has density

$$\frac{(\det T)^{(N_1 + N_2)/2}}{(\det \Sigma)^{-(N_1 + N_2)/2}} \exp(-1/2 \text{ tr } \Sigma^{-1} T), T \in H^+(p, \mathbb{D})$$
w.r.t. \( \nu_{\mathbb{D},p,N_1+N_2} \). The distribution of \( \nu(S_1, S_2) \) has density (86) w.r.t. a measure \( \kappa \) on \( \Lambda_p \) which is uniquely defined by

\[
(t, \tau)(\nu_{\mathbb{D},p,N_1} \otimes \nu_{\mathbb{D},p,N_2}) = \nu_{\mathbb{D},p,N_1+N_2} \otimes \kappa.
\]

Furthermore, \( \kappa \) has density

\[
(87) \quad \prod_{\gamma=1}^{p} \frac{\lambda_{\gamma}(1-\lambda_{\gamma})^{\delta(p-1)} R}{(\lambda_{\gamma}-\lambda_{\gamma})^{\delta}} \prod_{1 \leq \alpha < \beta \leq p} (\lambda_{\alpha}-\lambda_{\beta})^{\delta}
\]

w.r.t. a Lebesgue measure on \( \Lambda_p \).

**Proof.** The proof is analogous to the proofs for the other theorems.

For (87), one defines \( \tilde{r}(S_1, S_2) = (r(S_1, S_1+S_2), S_1+S_2 - r(S_1, S_1+S_2)) \), where

\[
r(R, T) = \sum_{j=1}^{m} a_j (RT^{-1})^{2j}.
\]

The determinant of

\[
dR = \sum_{j=1}^{m} a_j \sum_{k=0}^{2j} R^k dR^0 R^0^{2j-k},
\]

where \( dR \in H^+(p, \mathbb{D}) \) and \( R_0 = \Lambda \otimes I_\delta \), is

\[
\prod_{\gamma=1}^{p} Dr(\lambda_{\gamma}) \prod_{1 \leq \alpha < \beta \leq p} \left( \frac{r(\lambda_{\alpha}) - r(\lambda_{\beta})}{\lambda_{\alpha} - \lambda_{\beta}} \right)^{\delta}
\]

when \( 1 > \lambda_1 > \ldots > \lambda_p > 0 \).
8. THE NORMING CONSTANTS.

In Theorems 1-6 we have represented the distribution of the orbit projection \( \Pi \) by a density w.r.t. a Lebesgue measure on \( \Lambda_q \) for appropriate \( q \). This density is the product of the likelihood ratio statistic \( g \) and the density \( f \) of a measure \( \kappa \) with respect to that Lebesgue measure. (In Theorem 1, for example, the density of \( \Pi \) is the product of (18) and (21).) In order to find the density of \( \Pi \) w.r.t. the usual Lebesgue measure \( d\mu(\lambda) = \Pi d\lambda \), one must evaluate the norming constant \( (\int g(\lambda)f(\lambda)d\mu(\lambda))^{-1} \). We shall first evaluate the norming constants associated with Theorems 5 and 6 by a simultaneous recursion argument. The remaining norming constants are easily obtained from these.

We shall use the same notation as in sections 6 and 7. The distribution of \( \tau \) in Theorem 6 has density

\[
(88) \quad b(\delta, p, N_1, N_2) \prod_{\gamma=1}^{p} \frac{\delta(N_1-m)/2}{\lambda_{\gamma}} \left(1 - \lambda_{\gamma}\right) \prod_{1 \leq \alpha < \beta \leq p} (\lambda_{\alpha} - \lambda_{\beta})^2
\]

w.r.t. \( \nu \), where \( m = p - 1 + \frac{2}{\delta} \) and \( b(\delta, p, N_1, N_2) \) is the norming constant.

In fact, \( b \) is defined for all real values of \( N_1, N_2 \in [m, \infty) \). Let \( \nu_{\mathbb{D}, p} \) be an arbitrary invariant measure on \( H^+(p, \mathbb{D}) \). Then \( \nu_{\mathbb{D}, p, N}^0 = c(\delta, p, N) \nu_{\mathbb{D}, p} \), where \( c(\delta, p, N) \) is a constant. Since \( (t, \Pi)(\nu_{\mathbb{D}, p, N_1}^0 \otimes \nu_{\mathbb{D}, p, N_2}^0) = \nu_{\mathbb{D}, p, N_1+N_2}^0 \otimes b(\delta, p, N_1, N_2) f_\mu \), where \( f \) is given by (87), we obtain

\[
(t, \Pi)(\nu_{\mathbb{D}, p} \otimes \nu_{\mathbb{D}, p}) = \nu_{\mathbb{D}, p} \otimes \left[ \frac{b(\delta, p, N_1, N_2) c(\delta, p, N_1+N_2)}{c(\delta, p, N_1) c(\delta, p, N_2)} \right] f_\mu \]

It follows that

\[
(89) \quad b(\delta, p, N_1, N_2) = \frac{c(\delta, p, N_1) c(\delta, p, N_2)}{c(\delta, p, N_1+N_2)} k_1(\delta, p),
\]
where \( k_1(\delta, p) \) is a constant only depending on \( \delta \) and \( p \).

In Theorem 5, \( \Pi \) has density

\[
(90) \quad a(\delta, p_1, p_2, N) = \prod_{\gamma=1}^{p_2} \frac{\delta(p_1-p_2+1) - 1}{(1 - \lambda_\gamma^2)^{\delta(N-p+1)/2-1}} \prod_{1 \leq \alpha \leq \beta \leq p_2} (\lambda_\alpha^2 - \lambda_\beta^2)^{\delta}
\]

w.r.t. \( \mu \), where \( p = p_1 + p_2 \) and \( a(\delta, p_1, p_2, N) \) is the norming constant.

In the same manner as in the derivation of (89), it is shown that

\[
(91) \quad a(\delta, p_1, p_2, N) = \frac{c(\delta, p_1 + p_2, N)}{c(\delta, p_1, N)c(\delta, p_2, N)} k_2(\delta, p_1, p_2),
\]

where \( k_2(\delta, p_1, p_2) \) is a constant only depending on \( \delta, p_1, \) and \( p_2 \).

(Recall that \( v_{\mathbb{D}, p, N} = N^{\delta p N/2} \), \( c(\delta, p, N) = N^{\delta p N/2} \), \( c(\delta, p, N) = N^{\delta p N/2} \), \( c(\delta, p, N) = N^{\delta p N/2} \), \( c(\delta, p, N) = N^{\delta p N/2} \), \( c(\delta, p, N) = N^{\delta p N/2} \), \( c(\delta, p, N) = N^{\delta p N/2} \), \( c(\delta, p, N) = N^{\delta p N/2} \).

Since \( a(\delta, p, 1, N) = 2^\Gamma(\delta N/2)/(\Gamma(\delta p/2)\Gamma(\delta(N-p)/2)) \) and \( c(\delta, 1, N) = c(\delta, 2)^{N/2}/\Gamma(\delta N/2) \), where \( c_0 \) is a constant which depends on \( v_{\mathbb{D}, 1} \),

it follows by induction from (91) that

\[
(92) \quad c(\delta, p, N) = k_0(\delta, p)(\delta/2)^{Np/2}/d(\delta, p, N),
\]

where

\[
(93) \quad d(\delta, p, N) = \prod_{\gamma=1}^{p} \Gamma(\delta(N - \gamma + 1)/2)
\]

and \( k_0(\delta, p) \) is a constant only depending on \( \delta \) and \( p \).

If (92) is substituted into (89) one obtains
(94) \[ b(\delta, p, N_1, N_2) = \frac{k(\delta, p) d(\delta, p, N) d(\delta, p, N_1) d(\delta, p, N_2)}{d(\delta, p, N_1) d(\delta, p, N_2)} \]

where \( k(\delta, p) = k_0(\delta, p) k_1(\delta, p) \).

Since both sides of (94) are rational functions in \( N_1 \) and \( N_2 \) it follows that (94) in fact holds for all real values of \( N_1, N_2 \in [m, \infty) \). (It then follows that \( b(p, N_1, N_2) \) is defined for all real values of \( N_1, N_2 \in (p-1, \infty) \).)

By making the substitutions \( \lambda_1 = y_1 \) and \( \lambda_y = y_1 \gamma \), \( y = 2, \ldots, p \), in (88) and integrating over \( y_1 \) it is seen that \( b(\delta, p, p-1+\frac{2}{\delta}, p-1+\frac{2}{\delta}) = p \left( \frac{(p-1)}{2} + 1 \right) \left[ b\left( \delta, p-1, p-2+\frac{2}{\delta}, p+\frac{2}{\delta} \right) \right] \). If (94) is substituted into this expression one obtains after a reduction that \( k(\delta, p) = k(\delta, p-1) \Gamma(\delta/2) / \Gamma(\delta p/2) \), and it follows that \( k(\delta, p) = k_3(\delta) \left[ \Gamma(\delta/2) \right]^p / d(p, p) \), where \( k_3(\delta) \) is a constant only depending on \( \delta \). Since \( b(\delta, 1, N_1, N_2) = \Gamma(\delta(N_1 + N_2)/2) / (\Gamma(\delta N_1/2) \Gamma(\delta N_2/2)) \), it follows that \( k_3(\delta) \equiv 1 \), so that

(95) \[ b(\delta, p, N_1, N_2) = \frac{[\Gamma(\delta/2)]^p d(\delta, p, N_1 + N_2)}{d(\delta, p, p) d(\delta, p, N_1) d(\delta, p, N_2)} \]

Finally, by making the substitution \( y_\gamma = \lambda_\gamma^2 \), \( \gamma = 1, \ldots, p_2 \), in (90), one obtains that

(96) \[ a(\delta, p_1, p_2, N) \equiv 2^{p_2} b(\delta, p_2, p_1, N-p_1) \]

and that \( a(\delta, p_1, p_2, N) \) in fact is defined for all real values of \( p_1 \in (p_2-1, \infty) \) and all real values of \( N \in (p_1 + p_2 - 1, \infty) \).
It is now a simple matter to obtain the norming constants associated with Theorems 1–4. These are:

\[(97)\quad a(1,p+1,p,N+1) = 2^p b(1,p,p+1,N-p), \quad 2p \leq N,\]

\[(98)\quad a(2,p-[\frac{D}{2}] - \frac{1}{2}, \frac{D}{2}, N - \frac{1}{2}) = 2^p b(2,\frac{D}{2},p-[\frac{D}{2}] - \frac{1}{2},N-p+[\frac{D}{2}]), \quad p \leq N,\]

\[(99)\quad a(2,p+\frac{1}{2},p,N-\frac{1}{2}) = 2^p b(2,p+\frac{1}{2},p,N-p), \quad 2p \leq N,\]

\[(100)\quad a(4,p-[\frac{D}{2}] - \frac{1}{2}, \frac{D}{2}, N - \frac{1}{2}) = 2^p b(4,\frac{D}{2},p-[\frac{D}{2}] - \frac{1}{2},N-p+[\frac{D}{2}]), \quad p \leq N.\]

For each of the ten testing problems the \(\alpha\)'th moment, \(\alpha \geq 0\), of the likelihood ratio test statistic is readily obtained from these norming constants. For the problem associated with Theorem 1 one obtains

\[(101)\quad a(1, p+1, p, N+1) = \frac{d(1, p, N+1)d(1, p, N\alpha+N-p)}{\frac{p}{\Pi \gamma=1} \frac{\Gamma((N\gamma+2)/2)\Gamma((N\alpha+N-p-\gamma+1)/2)}{\Gamma((N\alpha+N-\gamma+2)/2)\Gamma((N-p-\gamma+1)/2)},}\]

and similarly for the problems associated with Theorems 2–6

\[(102)\quad \frac{p}{\Pi \gamma=1} \frac{\Gamma(N-\gamma+\frac{1}{2})\Gamma(N\alpha+N-p+[\frac{D}{2}]-\gamma+1)}{\Gamma(N\alpha+N-\gamma+\frac{1}{2})\Gamma(N-p+[\frac{D}{2}]-\gamma+1)},\]

\[(103)\quad \frac{p}{\Pi \gamma=1} \frac{\Gamma(N-\gamma+\frac{1}{2})\Gamma(N\alpha+N-p-\gamma)}{\Gamma(N\alpha+N-\gamma+\frac{1}{2})\Gamma(N-p-\gamma)}.\]
\[ \prod_{\gamma=1}^{[\frac{D}{2}]} \frac{\Gamma(2N - 2\gamma + 1)\Gamma(2(N\alpha + N - p + [\frac{D}{2}] - \gamma + 1))}{\Gamma(2N\alpha + 2N - 2\gamma + 1)\Gamma(2(N - p + [\frac{D}{2}] - \gamma + 1))} \]

\[ \prod_{\gamma=1}^{p_2} \frac{\Gamma(\delta(N - \gamma + 1)/2)\Gamma(\delta(N\alpha + N - p_1 - \gamma + 1)/2)}{\Gamma(\delta(N\alpha + N - \gamma + 1)/2)\Gamma(\delta(N - p_1 - \gamma + 1)/2)} \]

and

\[ \prod_{\gamma=1}^{p} \frac{\Gamma(\delta(N_1 + N_2 - \gamma + 1)/2)\Gamma(\delta(N_1\alpha + N_1 - \gamma + 1)/2)\Gamma(\delta(N_2\alpha + N_2 - \gamma + 1)/2)}{\Gamma(\delta(N_2\alpha + N_2 + N_1 - \gamma + 1)/2)\Gamma(\delta(N_1 - \gamma + 1)/2)\Gamma(\delta(N_2 - \gamma + 1)/2)} \]
